About the Editor

Steven G. Rogelberg, PhD, (Professor, Psychology and Organizational Science) serves as Director of Organizational Science and Director of Industrial and Organizational Psychology, as well as being the Founder/Director of Organizational Science Consulting and Research (outreach and consulting center), all at the University of North Carolina Charlotte. He has authored more than 50 publications and given more than 25 invited addresses/colloquiums addressing issues such as organizational research methods, team effectiveness, health and employee well-being, meetings at work, and organizational development. Besides serving as editor-in-chief on this two-volume series, he edited the *Handbook of Research Methods in Industrial and Organizational Psychology* (2002, 2004). Recent honors include being named Chair of Education and Training for the Society of Industrial and Organizational Psychology (SIOP), serving as Chair of SIOP's Katrina Relief and Assistance effort, serving as Guest Editor for Organizational Research Methods, being named SIOP Program Chair, receiving the 2001 Bowling Green State University (BGSU) Psi Chi Professor of the Year Award, serving as the 2000 BGSU graduation commencement speaker, receiving the BGSU Master Teacher Award, and being named a BGSU Alumni Research Fellow.

Dr. Rogelberg has received more than \$300,000 of external grant funding. He has held three international guest professor appointments, at the University of Sheffield, England; the University of Tel Aviv, Israel; and the University of Mannheim, Germany. Dr. Rogelberg currently provides ad hoc reviews for a number of journals, as well as the National Science Foundation, and serves or has served on the editorial board for *Journal of Management*; *Group Dynamics: Theory, Research, and Practice*; the *SIOP Professional Practice Book Series*; and *The Industrial Psychologist*. His research has been profiled on public television, on public radio (NPR, CBC), and in newspapers (e.g., *Chicago Tribune*, *Los Angeles Times*, *Wall Street Journal*, *London Guardian*). Companies for whom he has provided consulting services include IBM, Grace Cocoa, National Society for Black Engineers, Procter & Gamble, Brush Wellman, Marathon Ashland Petroleum, Center for Self-Directed Work Teams, Toledo Area Regional Transit Authority, Mid-American Information Services, and Marshall-Qualtec. Before completing his PhD in Industrial/Organizational Psychology at the University of Connecticut in 1994, he received his undergraduate BSc degree from Tufts University in 1989.

Personnel Management Decisions

Introduction

THE FIELD

Psychology is the scientific study of the human mind and behavior. Industrial/organizational (I/O) psychologists focus the lens of psychological science on a key aspect of human life, namely, their work lives. In general, the goals of I/O psychology are to better understand and optimize the effectiveness, health, and well-being of both individuals and organizations.

The specific topics of study in I/O psychology include but are not limited to the following:

- *Team and organizational effectiveness*—organization culture and climate, group dynamics, cross-cultural issues, customer service, labor relations
- *Employee recruitment, selection, and promotion*—recruitment practices, selection strategies and systems, assessment centers, selection process fairness, hiring, consultation and expert testimony on Equal Employment Opportunity and Affirmative Action (EEO/AA)
- *Individual differences, measurement and testing*—human cognitive abilities, physical abilities, personality dispositions, vocational interests, test theory and scale construction, validity and validation strategies
- *Training and development*—executive coaching, management development, training
- *Performance management*—design of job performance measurement systems for feedback and performance improvement, performance appraisal and management
- *Workplace health*—ergonomics, human factors, and safety; overcoming stress; Occupational Safety and Health Administration (OSHA)
- *Employee attitudes and satisfaction*—empowerment, retention, job satisfaction, conflict and stress management, aging and retirement, turnover, organizational commitment

- *Compensation and benefits*—pay, perks, rewards, recognition
- *Communication effectiveness*—organizational communication design, processes, and effectiveness; technology-facilitated communications
- *Employee motivation*—factors that motivate employees, job design and evaluation
- *Change management*—mergers and acquisitions, process reengineering, productivity and quality improvement, downsizing
- *Employee citizenship and deviance*—harassment, bullying, prosocial behavior, violence

Given that I/O psychology is both a science and a practice, enhanced understanding of the foregoing topics leads to applications and interventions that benefit individuals, organizations, and the communities in which people live and work.

The field is experiencing tremendous growth. Take, for example, the following data. Over the 18-year span from 1986 to 2004, there has been a nearly 50% increase in I/O doctoral programs and a greater than 200% increase in I/O master's programs. Membership in the Society for Industrial and Organizational Psychology (SIOP), the principal professional organization of I/O psychologists, has increased more than 65% since 1991. Attendance at the annual SIOP conference has increased 400% in the last 20 years and is now approaching 4,000 attendees. Arguably, I/O is the fastest growing area of psychology.

This growth has been spurred in part by the steadily increasing demand for the services of I/O psychologists. Employment surveys have been taken for many years by SIOP. For the last 25 years, these surveys have consistently indicated near zero unemployment for the society's membership, a clear

indicator of the need for I/O psychologists. The American Psychological Association's *Report of the Employment Status of 1997 Graduates* and the follow-up *Report of the Employment Status of 2001 Graduates* show that I/O psychologists composed the highest proportion of individuals employed full-time (lowest unemployment rates), compared with other fields of specialization (health service provider, social/personality, developmental/educational, physiological/experimental).

RATIONALE FOR ENCYCLOPEDIA

Though the extraordinary growth of I/O psychology over the last two decades signals the vibrancy of this field, it has also created a void in the literature. With the ever-widening range of topics studied, no single extant reference source captures the diversity and sophistication of the field. In addition, with the increasing visibility of I/O psychology, there is a growing need for a resource appropriate for experts but accessible to nonexperts. The *Encyclopedia of Industrial and Organizational Psychology* was designed to fill this void.

The *Encyclopedia* is designed to be an introduction to the topics of I/O psychology for an audience including undergraduate students, beginning graduate students of I/O psychology and related disciplines, lay audiences seeking a nontechnical description of the field and its practices, practitioners wishing to stay abreast of the changes and updates in the field, and even the PhD-level academic seeking a portal into a new specialty area. It should also be noted that although the *Encyclopedia* is designed to be comprehensive in its coverage of topics, it is not meant to provide comprehensive treatments of any given topic.

CONTENT AND ORGANIZATION

There was an explicit effort to cover every topic that is currently studied by I/O psychologists. This is, of course, a lofty and complex goal, in that it is probably impossible ever to have unanimous consensus on what would constitute such a list. Nonetheless, we have tried to be as comprehensive as possible without being overly redundant. To accomplish this, all entries include several associated topics and cross-references. In some cases, a topic that was covered in the context of a larger topic did not receive its own entry; in those cases, the smaller topic is listed with a cross-reference to the entry in which it is discussed.

To help the reader navigate the *Encyclopedia*, a Readers Guide is provided, organizing the content into four parts comprising 14 sections. Additionally, there is a list of the entries are presented in alphabetical order.

As noted earlier, the content of each entry is designed to be a concise summary of the major aspects of the topic. Further, there was an explicit effort to have the entries written in a nontechnical manner so that they would be accessible to the novice. Each entry is designed to provide the reader with a basic description of the topic that will provide a foundation in that area. Following each entry is a Further Reading section that can take the reader to the next level.

HOW THE ENCYCLOPEDIA WAS CREATED

The *Encyclopedia* was developed in six basic steps:

Step 1—Leading I/O psychologists around the world were invited to serve on the senior editorial board. The senior editorial board includes editors of the field's top journals, prolific researchers, and other leaders in the field. The senior editorial board also includes the associate editor, Dr. Charlie L. Reeve, who represents one of the top young talents in the discipline and a future leader.

Step 2—We created a master list of topics for the book. This step involved two primary parts. First, an initial list of topic headwords was assembled by the editor and associate editor. To do this, we did a page-by-page search of eight major I/O psychology textbooks and handbooks. Then, we went through the last three years of the top I/O journals to cull additional topics. This draft list was then reviewed by the entire senior editorial board, which made a series of additions and subtractions. It should be noted that we explicitly made an effort to include topics that are not readily found in published sources to date, but that we felt were just on the cusp of becoming mainstream given their treatment in recent journal articles. Time will tell the extent to which we have accurately forecast the viability of these topics.

Step 3—We identified and invited contributors. The senior editorial board was first asked to nominate individuals to author the list of entries. We also searched PsychINFO to find people publishing on certain topics, and we consulted with our colleagues for additional suggestions.

Just as we wanted the content of the *Encyclopedia* to accurately reflect the content of the field of I/O psychology, we sought to recruit a collection of contributors that would represent our population. As such, we invited authors from all career stages, ranging

from promising young doctoral students to some of the most well-known and talented luminaries in our field. Likewise, we invited a mix of leading academics and practitioners from around the world. In this sense, we believe the list of contributors itself is a valuable resource, a virtual who's who (or in some cases, a "who will be who") of I/O psychologists.

Based on this initial list, we then invited individuals to contribute. We were pleasantly surprised by the phenomenal acceptance rate in the first round of invitations. In relatively few cases did people decline (usually due to time commitments).

Step 4—Contributors were given basic guidelines and instructions regarding the writing of their entries. In particular, we encouraged them to be thorough in describing the entire topic area and to write in nontechnical, accessible language.

Step 5—The editor and associate editor then reviewed all the entries and asked authors for revisions as necessary.

Step 6—We finalized the volumes and compiled the appendixes.

ACKNOWLEDGMENTS

The existence of this *Encyclopedia*, and in particular its high level of quality, is a testament to the efforts of a large number of extraordinary people. First, I would like to thank the senior editorial team, with special recognition to my excellent associate editor Charlie Reeve. I am also indebted to the talented publishing

team at Sage, whose high levels of professionalism and efficiency were much appreciated. Thanks also go to Molly Behringer and Shannon Randall for their administrative help. And, of course, I would like to thank the first-rate scholars and professionals who authored the entries.

I also appreciate the advice, counsel, and friendship of my current and former colleagues in I/O psychology and organizational science at the University of North Carolina Charlotte: Anita Blanchard, Kimberly Buch, David Gilmore, Eric Heggstad, Jo Ann Lee, Charlie Reeve, William Siegfried, Jennifer Welbourne, Chris Henle, Doug Pugh, Beth Rubin, Kelly Zellars, Yang Cao, Teresa Scheid, Wei Zhao, Shawn Long, Clifton Scott, John Kello, Scott Tonidandel, and Ben Pepper.

I also thank the Department of Psychology and Chair Brian Cutler for supporting this endeavor. I also wish to extend deep gratitude to my Studio B literary agent Neil Salkind for his wisdom and mentorship.

On a personal level, I want to thank my wife, Sandy Rogelberg, for her love, her balance, and her unyielding support. I would like to thank my brother, David Rogelberg, for making book publishing a reality for me and being a source of inspiration. I would like to thank my mom, Jane Rogelberg, and dad, Joel Rogelberg, for, well—everything. I also want to thank the best friend a person can have, Peter Kahn.

—Steven G. Rogelberg

A

ABUSIVE SUPERVISION

Abusive supervision refers to sustained displays of nonphysical forms of hostility perpetrated by supervisors against their direct reports. Examples of behavior that fall within the abusive supervision content domain include public derogation, undermining, and explosive outbursts. Key features of the construct are that abusive supervision refers to ongoing manifestations of hostility rather than discrete episodes and that abusers may or may not intend to cause harm. Hence, for example, yelling at subordinates for the purpose of eliciting greater task performance could be considered abusive. It should also be noted that abusive supervision constitutes a subjective assessment, in the sense that behavior that is perceived to be abusive in one context may not be so perceived in another context, and two subordinates could render different interpretations of the same supervisor behavior. Similar concepts that have been the focus of systematic empirical research include bullying, petty tyranny, and downward mobbing.

EPIDEMIOLOGY

According to epidemiological studies, abusive supervision is much more common than physical violence or sexual harassment; one in seven employees reports that his or her current supervisor is abusive, approximately 50% of employees can expect to have an abusive supervisor at some point in their working life, and most abusers target multiple subordinates simultaneously. Half of abusive supervisors are women, most

abusers target same-sex victims, and there are sex differences in terms of the ways in which men and women abuse their subordinates; women bullies engage in more social manipulation (i.e., rumors and insulting comments about one's personal life), and male bullies engage in more covert aggression, acts that on the surface appear rational, such as appraising targets unfairly and preventing them from expressing themselves.

OBSTACLES TO SYSTEMATIC EMPIRICAL INQUIRY

There are challenges associated with studying abusive supervision, not the least of which is the fact that researchers typically rely on subjective reports as to individuals' level of exposure. A problem with this approach to measuring abusive supervision is that some people may underreport their level of exposure because they are reluctant to admit that they have been victimized, whereas others exaggerate their supervisors' hostility. A related obstacle to conducting valid empirical research is that linking abusive supervision and important outcomes requires gathering data from abused subordinates who are willing to identify themselves. Failing that, perceived abuse cannot be linked with data collected from independent sources (e.g., observers, supervisors, archival records). A third challenge is that organizations may be hesitant to allow researchers to administer surveys on the topic. What is clear is that although abusive supervision is a low-base-rate phenomenon that is difficult to study, the research to date consistently suggests that its effects can be severe.

CONSEQUENCES OF ABUSIVE SUPERVISION

Compared with nonabused subordinates, abused subordinates have higher quit rates, and among those who stay in the job, abusive supervision is negatively related to subordinates' job satisfaction, commitment to the organization, and trust in the supervisor, and positively related to psychological distress (i.e., depression, anxiety, and burnout) and conflict between work and family obligations. The cost per serious case of abuse in the workplace has been estimated at between \$17,000 and \$24,000 in terms of absenteeism, turnover, legal costs, and reduced productivity, and the total cost to organizations has been estimated to be more than \$23.8 billion in the United States alone.

Abusive supervision is not strongly related to bottom-line measures of productivity such as sales volume, number of units produced, and work quality. The most likely reason for this is that employees cannot easily modify these kinds of performance contributions, regardless of how they might feel about their boss. For example, assembly-line workers cannot simply stop producing when they do not like something at work, and salespeople on commission cannot stop selling to get back at their boss, at least not without hurting themselves. But research suggests that abused subordinates will retaliate against their supervisor and their organization by withholding citizenship behaviors, contributions such as being helpful and courteous, and showing initiative. Abused subordinates can express their resentment by modifying their citizenship behavior, because these contributions are to a large extent discretionary, meaning that they fall beyond the job requirements. These kinds of contributions are very important because they provide organizations with flexibility and the capacity to cope with uncertainty. Hence, organizations may be at a competitive disadvantage when a substantial percentage of subordinates withhold citizenship because their supervisors are abusive.

Although abused subordinates tend to perform fewer acts of citizenship than do nonabused subordinates, some abused subordinates will nevertheless do so. However, there are differences in the ways abused subordinates respond to their coworkers' citizenship performance. Intuitively, we would expect that employees will have more favorable attitudes toward their job when their coworkers perform more acts of citizenship. This notion is rooted in the assumption that

good citizenship makes the workplace a more attractive and comfortable environment. However, it was found that this was not the case for work groups in which the supervisor was more abusive. In those instances, employees were less satisfied when their coworkers engaged in greater citizenship behavior. Subsequent inquiry explained why this was so. In groups led by abusive supervisors, subordinates performed citizenship behaviors not out of a genuine desire to benefit the organization, but to portray themselves in a favorable light, to make their coworkers look less dedicated by comparison, and to direct their supervisors' hostility at others. Consequently, acts of citizenship may cause fellow coworkers to experience unfavorable attitudes when the supervisor is abusive.

MODERATING FACTORS

Abusive supervision does not affect all employees the same way. In three studies, it was found that the deleterious effects of abusive supervision on employees' attitudes and psychological health were more pronounced when the subordinate has less job mobility (i.e., when the subordinate is trapped in a job because he or she has few attractive alternatives to the current position), when the abuse is selective rather than distributed (i.e., when subordinates are singled out for abuse as opposed to being targeted along with others), and when the target attributes the abusive behavior to stable characteristics of the supervisor (e.g., meanness, incompetence, or indifference) rather than to characteristics of the organization (e.g., time pressures or competitive work climates).

Another study found that subordinates' personalities influenced how they responded to abusive supervision. This study suggested that abused subordinates were more likely to engage in dysfunctional forms of resistance (i.e., nonconformity to downward influence attempts that involves outright refusal and ignoring the supervisor's requests) and that this effect was more pronounced among subordinates who were dispositionally disagreeable (i.e., unconcerned about the quality of their interpersonal relationships with coworkers) and dispositionally low in conscientiousness (unconcerned about fulfilling task-related obligations). This research provides support for the idea that subordinates' personalities influence the extent to which they engage in retaliation behaviors against abusive supervisors; employees retaliate against

abusive supervisors by actively refusing to do what their supervisors want them to do, but only when they are unconcerned about the relational and task-related consequences associated with noncompliance.

ANTECEDENTS OF ABUSIVE SUPERVISION

Comparatively little research has explored the antecedents of abusive supervision. One study revealed no consistent relationships between hostile supervisor behavior and supervisor disposition (e.g., theory X beliefs, low self-esteem, and low tolerance for ambiguity), situational factors (e.g., institutionalized norms, power, and stressors), or their interactions. A more promising line of inquiry has taken a victim-precipitation perspective, the notion that some individuals may become at risk of being victimized by eliciting or provoking the hostility of potential perpetrators and that perpetrator and situational factors contribute more strongly to the occurrence of abusive supervision when a vulnerable target is available. The study in question found that supervisors who experienced procedural injustice (i.e., decision makers using unfair procedures during the process of rendering allocation decisions) were more abusive when they had a high negative-affectivity subordinate, one who was dispositionally inclined to experience high levels of distressing emotions and who was likely to be perceived as weak, vulnerable, and ripe for exploitation. An implication of this finding is that supervisors inclined to hostility choose targets strategically, focusing their abuse on subordinates who appear to be “good” targets. This work also suggests that perpetrators may express their hostility against targets other than the source of their frustration (i.e., subordinates who are not responsible for the injustices supervisors experience).

COPING WITH ABUSIVE SUPERVISION

Is there anything abused subordinates can do to cope with their supervisors’ hostility? Abused subordinates use two general kinds of coping strategies, which may be labeled *avoidant coping* (physical and psychological withdrawal, maintaining physical distance, not coming to work, and reliance on drugs and alcohol) and *active coping* (directly communicating injustices to the supervisor). Research suggests that abused subordinates are more likely to use avoidant coping

than active coping but that the use of active coping is a more effective strategy; in a 6-month longitudinal study, it was found that the relationship between abusive supervision measured at Time 1 and psychological distress (i.e., burnout, anxiety, and depression) measured at Time 2 was stronger when subordinates used avoidant coping and weaker when subordinates used active coping. That is, active coping buffered the stressful effects of abusive supervision and avoidant coping exacerbated those effects.

CONCLUDING COMMENTS

Given the significant costs that abusive supervision can have for organizations and their members, organizations would be well-advised to take it seriously. This involves a two-pronged effort focusing on both (a) prevention and (b) management of abuse when it does occur. Organizations can prevent the occurrence of abusive supervision by fostering a culture of civility that is incompatible with abusive behavior. This can be accomplished by implementing 360-degree feedback programs and training employees and managers to develop the skills needed to provide and to openly receive constructive feedback. Where abuse occurs, organizations can manage its effects by developing disciplinary procedures for those who violate the norms for acceptable interpersonal behavior, encouraging victims and witnesses to come forward, and sending the message that those claims will be taken seriously. The evidence suggesting that direct coping produces more favorable outcomes than avoidant coping means that it may be fruitful to encourage rank-and-file employees to bring abusive behavior to the attention of higher authorities. In addition, managers should be trained to spot some of the markers for abusive behavior, such as withdrawal behaviors, low morale, and distrust.

ACADEMY OF MANAGEMENT

The Academy of Management is the oldest and largest scholarly professional management association in the world. Founded in 1936 by professors Charles L. Jamison and William N. Mitchell, the academy was formed to create and exchange knowledge about the discipline of management. Broadly defined, this diverse field ranges from the study of organizational processes, structures, and behaviors to the examination of environmental, cultural, industrial, and economic factors that affect organizations and their employees.

Located at Pace University and the Lubin School of Business in New York, the Academy of Management is a member-driven association led by a 16-member board of governors, elected by voting members of the academy. Committees and task forces are appointed by the president of the academy to carry out services and conduct projects for the association.

The Academy of Management has 24 professional divisions and interest groups, and members belong to a minimum of 2 of these groups. The divisions with the most (i.e., more than 2,500) active members include Organizational Behavior; Business Policy and Strategy; Organization and Management Theory; Human Resources; Organizational Development and Change; and International Management. Liaisons

communicate between the board and the academy's committees, task forces, divisions, and interest groups.

MEMBERSHIP

The Academy of Management comprises more than 15,700 members from 90 countries. Its membership includes researchers from colleges, universities, and research organizations, as well as practitioners who work in businesses, government agencies, and not-for-profit organizations. Although there are no requirements to become a member, those interested in joining the academy must apply to one of four membership categories: (a) academic (e.g., researcher, teacher); (b) executive (e.g., management, consultant); (c) student; and (d) emeritus (i.e., member for at least 10 years prior to retirement). A majority of the membership is in the academic category.

MISSION

The mission of the Academy of Management is to enhance the profession of management by advancing the scholarship and enriching the professional development of its members. The academy is also dedicated to shaping management research and education. Several core values guide the achievement of this mission: (a) to conduct and share high-quality research, teaching, and practical applications of management; (b) to promote and encourage ethical conduct in activities pertaining to management research, teaching, and practice; (c) to foster an environment that respects diverse points of view; (d) to encourage members to share their knowledge of management and new developments in the field with members located in different institutions and countries; and (e) to build opportunities for professional collaboration and networking to advance the field.

FUNCTIONS

The Academy of Management sponsors a number of activities in pursuit of its mission. Each year, the academy holds an annual meeting, which is attended by more than 6,000 people. This meeting provides a setting in which to share research and expertise in all disciplines of management via invited papers, competitive paper sessions, panel discussions, symposia, workshops, eminent speakers, and special sessions for doctoral students.

In addition, the Academy of Management publishes a variety of management-related periodicals. Among these publications are four scholarly journals: (a) *Academy of Management Learning and Education*, (b) *Academy of Management Journal*, (c) *Academy of Management Review*, and (d) *Academy of Management Executive*. The Academy of Management also publishes a newsletter and a best papers proceedings CD from its annual meeting. Each division within the academy disseminates newsletters for its members, as well.

In terms of electronic communications, the Academy of Management hosts a wide variety of listservs, in which interested parties can post or view messages about the full spectrum of management topics. Several online discussion boards are also hosted by the academy.

Another program offered by the academy is a career development and job placement service. Job interviews and career growth workshops are conducted at the conference, and a searchable database system is offered for organizations to post positions and view applicant credentials, and for potential applicants to search for available positions. Professional development opportunities are also available through forums on special topics considered timely and important to members of the academy. Further, in recognition of contributions to the field, the Academy of Management sponsors a number of professional awards for notable achievement.

ACTION THEORY

Action theory represents a general model of work-related cognition and behavior with implications for a wide range of topics in industrial/organizational psychology. Inspired by Lewin's field theory, American cybernetic models, and Russian and Polish

approaches, German work psychologists initiated the development of action theory in the late 1960s. As the core concept of the theory, action is conceived of as goal-directed behavior. Actions are behavioral units oriented toward their own distinct goals, whereas operations (e.g., movement patterns) are subordinate action components. As anticipatory cognitive structures, goals guide the action process, because they function as relatively invariant set points for the interpretation of feedback. Action theory explains both the sequential ordering and the hierarchical structuring of action.

THE ACTION SEQUENCE

Action theory differentiates five phases of the action sequence: (a) goal development and choosing between competing goals; (b) orientation (i.e., collecting relevant information about the task and the conditions in one's work environment) and prognosis of future events; (c) plan development and selection; (d) execution of the plan and monitoring; and (e) the processing of feedback, which in turn influences the development of subsequent goals. These action steps are not always taken in the same order (e.g., initial plans may be refined during action execution). The action sequence allows for an analysis of the interface between the objective work environment and subjective task representations, because employees' specific redefinitions of tasks presented by the organization (e.g., to operate a machine) determine their individual goals and plans (e.g., whether and how to take action when the machine breaks down).

FOUR LEVELS OF ACTION REGULATION

From a structural point of view, actions are organized hierarchically, because higher-order goals are broken down into subgoals, and higher levels of conscious intellectual regulation are superordinate to lower levels of automatic operations. Recent versions of action theory distinguish four levels of action regulation, ordered from lowest to highest:

1. *Sensorimotor level*. Stereotyped and automatic movement sequences are organized without conscious attention.
2. *Level of flexible action patterns*. Ready-made action schemata that do not require conscious representation are tailored to situationally defined parameters.

3. *Intellectual level.* New actions in a complex environment are consciously regulated.
4. *Heuristic level.* Metacognitive strategies such as general problem-solving approaches are pursued either consciously or automatically.

THE OPERATIVE IMAGE SYSTEM

One's accumulated knowledge of the relationships between specific conditions, actions, and results is stored in the so-called operative image system. This system reflects the cognitive base for action regulation and entails long-term representations of schemata or strategies applicable to action regulation at all four levels (e.g., movement-oriented schemata to be regulated at the sensorimotor level, and strategies to be implemented at the intellectual level). Originally, cyclical test–operate–test–exit (TOTE) units, which imply that action is taken until there is congruity between the current state and a criterion, were considered the basic units of action regulation. To reconcile this classic discrepancy reduction approach with the notion of discrepancy creation, action theorists have emphasized the role of goals as desired end states and the impact of active approaches on the environment.

APPLICATIONS OF ACTION THEORY

Action theory has implications for several domains, including stress, training, job analysis, work design, error management, emotion regulation, competence development, and personality enhancement. Action theorists emphasize socialization processes by considering malleable facets of personality, motivation, and cognitive ability as dependent variables that may be affected by work action. For example, work environments encouraging forward thinking induce action styles such as planfulness (i.e., the detailed development and persistent implementation of long-range plans). New ideas on error management and the function of errors in the learning and training process were also derived from action theory. Research examining why so-called superworkers produce superior results without spending more time at work revealed that they engage more frequently in planning and have better operative image systems, reflected in greater knowledge of error frequencies, the signals indicating errors, and the duration and efficiency of different strategies of dealing with errors.

Conceptualizing stress as a disturbance of action regulation, action theory offers a theoretically grounded stressor taxonomy, composed of three categories: (a) regulation obstacles (i.e., interruptions and regulation difficulties such as poor visibility or lack of information); (b) regulation uncertainties (e.g., role ambiguity); and (c) overtaxing regulations (e.g., time pressure). Multiple job analysis tools have been developed based on action theory. These tools typically provide a structured assessment of regulatory requirements and difficulties (e.g., the degree to which the work requires a conscious development and coordination of new plans). The function of emotions for action regulation, particularly in service work, has also been analyzed within an action theory context. Emotions enable people to continue with the action process despite barriers and difficulties. Examples are the motivation derived from pride in anticipation of goal attainment and the role of negative affect in facilitating an objective assessment of environmental barriers.

THE VALUE OF ACTION THEORY

As an integrative metatheory, action theory illuminates the implications of specific cognitive and social psychological theories for industrial/organizational issues. For example, studies based on the theories of action-state orientation and self-discrimination revealed that distractible state-oriented individuals are less likely to efficiently translate intentions into action and more likely to falsely redefine external demands as their own goals. Action theory also helps explain the impact of societal transformations on work activities. Longitudinal research based on action theory demonstrated that increases in the levels of complexity and control experienced by East German employees after the country's reunification enhanced their personal initiative (i.e., organizationally functional forms of self-started, proactive, and persistent behavior).

In conclusion, action theory distinguishes itself from most micro industrial/organizational models because of its scope, its versatility, its theoretical foundation in cognitive science, its applicability to various facets of everyday work behavior, and its simultaneous consideration of objective environments, internal mental operations, and observable behavioral outcomes. By bridging the gaps between the environment and cognition (e.g., via task redefinitions in the action sequence) and between cognition and action (e.g., via plans as starting points for

action), action theory integrates cognitivist and behavioral approaches. Action theory has been described as a way of thinking that leads to a sharper understanding of how our cognitive apparatus is used and shaped in the workplace and in relation to the world we inhabit.

ADVERSE IMPACT/DISPARATE TREATMENT/DISCRIMINATION AT WORK

The phrase *to discriminate* has two interpretations: (a) to display prejudice toward members of a group through unjustified negative actions, and (b) to meaningfully differentiate between people on the basis of their characteristics. Discrimination of the second form involves the ability to ascertain the presence and degree of characteristics that distinguish one person from another. For example, a classical music critic should *discriminate* among pianists on the basis of technique and interpretation. This interpretation holds that it is meaningful to differentiate an exceptional

performer from an average performer on the basis of relevant factors. In contrast, discrimination of the first form invokes notions of preference and social injustice. Meaningful differentiation is decidedly absent as people are distinguished based on demographic, nonrelevant factors. Because individuals differ on the basis of many characteristics, organizations must regularly discriminate between individuals when hiring, allocating resources, and rewarding to effectively manage a workforce. When organizations differentiate individuals based on job-relevant or organization-relevant factors, this discrimination is meaningful and warranted. When organizations instead differentiate individuals on the basis of stereotypes and allow that differentiation to influence decision making, the organization has engaged in workplace discrimination.

PERCEPTUAL FORCES BEHIND DISCRIMINATION

The approximately 80,000 complaints filed annually with the Equal Employment Opportunity Commission (EEOC) indicate that employment discrimination is common. Sex and racial biases influence performance appraisals and promotion decisions. Black and Hispanic applicants tend to receive less favorable evaluations during interviews. Interpersonal discrimination—avoiding, distancing, and excluding members of a group—regularly limits minority group members' access to developmental mentors and networks and interferes with workplace productivity. Further, reports continue to document the presence of a “glass ceiling” that blocks women and racial minorities from gaining leadership positions in organizations.

The perceptual processes theorized to produce discriminatory behavior explain part of why discrimination at work persists. For individuals, discrimination originates with the need to sort people into personally meaningful categories as a means of efficiently processing the myriad perceptual stimuli encountered each day. This social categorization is often based on whether a person is perceived by the individual to be similar or different, and it is facilitated by stereotypic beliefs that a person categorized within a specific group possesses certain traits purely because he or she is a member of that group. For example, a female candidate for a management-level position may be passed over for promotion if the stereotype held by evaluators leads them to assume that she will become emotional when under stress. As illustrated, the categorization

process influences how individuals evaluate and feel about other people. Persons categorized as members of one's own group invoke more favorable reactions, whereas persons categorized as members of another group invoke less favorable responses.

However, the tendency to categorize others does not necessarily translate into discriminatory actions. Various individual and contextual variables, such as the social composition of the workplace, the salience of group membership, and the presence of organizational and local norms, will either facilitate or impede the emergence of discriminatory behavior.

EMPLOYMENT DISCRIMINATION LAW

The legal environment also plays an important role in managing the occurrence of discriminatory behaviors. Federal, state, and municipal statutes, as well as various constitutional amendments and executive orders, afford individuals rights and protection in the event that they are discriminated against in an employment setting or are involved in any way in an employment discrimination suit. The three primary pieces of federal legislation responsible for regulating discrimination at work are the Civil Rights Act, the Americans With Disabilities Act, and the Age Discrimination in Employment Act.

The Civil Rights Act

The Civil Rights Act (Title VII, 1964, and as amended in 1978 and 1991) prohibits organizations with 15 or more employees from discriminating against individuals on the basis of race (e.g., Caucasian, African, and Asian), ethnicity (e.g., Hispanic), color of skin, national origin (e.g., Mexican), sex (and pregnancy or pregnancy-related medical conditions), and religion in all aspects of employment (e.g., hiring, compensation, training, performance management, discharge). The act defined a *protected group* as a class of individuals who are similar on one of these bases. However, protected group membership is context-specific. For example, a male applicant for an accountant position may not be considered a minority group member in that context, but he would likely be considered a protected group member if he applied for a flight attendant position. Thus, the appropriateness of identifying certain individuals as minorities depends on the demographic makeup of the applicant pool, current jobholders, and the relevant labor market.

Title VII explicitly allowed for discriminating between individuals on the basis of a job-related, meaningful reason or in response to a bona fide seniority system. The act also required organizations to provide reasonable accommodation for employees to engage in religious practices, unless doing so would pose an undue hardship. The act created the EEOC, the federal agency charged with enforcing the provisions of employment discrimination legislation. As amended, the act banned the adjustment of assessment scores, whether gathered for purposes of promotion, training, or selection, on the basis of protected class status; lessened the impact of a mixed-motive defense for organizations wherein legitimate reasons in justification of a discriminatory action are rendered in conjunction with unlawful reasons; and limited the ability of individuals to allege reverse discrimination in the context of judicially approved affirmative action plans.

The Americans With Disabilities Act

The Americans With Disabilities Act (Title I, 1990) prohibits organizations with 15 or more employees from discriminating against disabled individuals, individuals who have a record of a disability, and individuals perceived to be disabled in all aspects of employment. Disabled individuals are defined as those persons who suffer from a physical or mental impairment that is not correctable and substantially limits at least one major life activity, such as thinking or standing. For example, a legally blind individual who requires the assistance of a seeing-eye dog would be considered disabled, but a legally blind individual whose vision can be corrected by wearing glasses would not. Essentially, the verification of a disability must go beyond a medical diagnosis to consider how that condition affects an individual's daily life.

Organizations are required to provide reasonable accommodation to disabled individuals who are otherwise qualified to perform the essential (i.e., most integral or critical) functions of the job. This may mean, for example, adjusting break times so that a diabetic may stop work to conduct necessary insulin tests. An accommodation that would involve excessive expense relative to an organization's resources, dramatically alter the job or business in question, violate current organization systems or policies (e.g., seniority systems), or represent a direct threat to the health and safety of other workers may be viewed as an undue hardship for the organization and hence deemed

unreasonable. Thus, the reasonableness of a given accommodation is individual-, organization-, job-, and context-specific. Although the disabled individual is initially responsible for requesting accommodation, the organization and the individual are encouraged to work together to identify possible accommodations.

The Age Discrimination in Employment Act

The Age Discrimination in Employment Act (1967) prohibits organizations with 20 or more employees from discriminating against individuals age 40 and older in all aspects of employment. Similar to Title VII, the act explicitly allowed for discriminating between individuals in the presence of a rational, job-related reason. In addition, the act identified a series of policy exemptions wherein an age requirement would be viewed as lawful. These include (a) organization policies that identify a mandatory retirement age of 65 for bona fide executives, (b) state or local statutes that establish a mandatory retirement age for police officers and firefighters, and (c) various age restrictions in the commercial airline industry. The act also prohibits age-based discrimination even when the individuals involved are both within the age-based protected class; for example, an individual who is 60 can allege discrimination in favor of an individual who is 45.

TYPES OF EMPLOYMENT DISCRIMINATION

When these laws are violated, an individual may seek legal redress by filing a claim of discrimination with the EEOC. Assuming the claim has merit, the EEOC will pursue conciliation with the offending organization to settle the dispute. If attempts at conciliation fail, the suit will proceed to the court system. The overwhelming majority of complaints are resolved before reaching federal court. Complaints that do reach a courtroom proceed through a series of phases in which the burden of proof is shifted back and forth between the plaintiff (the individual allegedly discriminated against) and the organization. The process through which that burden is met depends on the type of discrimination alleged.

Disparate Treatment

Disparate treatment occurs when an individual suffers intentional discrimination on the basis of his or

her membership in a protected group. For example, after September 11, 2001, the EEOC experienced an increase in the number of complaints filed by Arab Americans and Muslims who experienced harassment or discharge allegedly on the basis of their national origin or religion. Proving that the organization had intent or motive to discriminate is a central aspect of a disparate treatment lawsuit. Because intent can rarely be known, disparate treatment must often be inferred on the basis of circumstantial evidence. To establish a prima facie case of discrimination, the plaintiff must prove that he or she was differentially treated because of membership in a protected group. This may be accomplished by demonstrating that members of a specific protected group consistently received disproportionately unfavorable actions.

Under a pattern-and-practice claim, this may be accomplished by demonstrating that members of a specific protected group consistently received disproportionately unfavorable actions. Under the McDonnell Douglas/Burdine framework, this may be accomplished by showing that the plaintiff was adversely treated relative to an individual of a different group who was otherwise similarly situated in terms of qualifications and job-related circumstances.

In response, the organization must provide a legitimate, nondiscriminatory reason for its actions. The organization may argue that the plaintiff did not have the necessary job-related qualifications or display the expected level of performance. In a case of disability discrimination, the organization may argue that the requested accommodation was unreasonable. Or the organization may defend the action by stating that the decision was based on a bona fide occupational qualification (BFOQ). Through BFOQs, organizations may overtly exclude individuals on the basis of sex, age, religion, or national origin when such exclusion is required for business survival and/or public and personal safety. A BFOQ assumes that most individuals within a given protected group will be unable to execute a central job requirement and that failure to do so will risk the health of the organization and the broader public. For example, air traffic controllers may not be older than age 49. In the event that the organization successfully puts forth an acceptable justification, the plaintiff may establish that the proffered reason is merely a pretext and that discrimination was the true reason behind the action.

Adverse (Disparate) Impact

Adverse (disparate) impact is discrimination that occurs when members of a protected group are systematically excluded based on an employment policy or practice that is neutral on its face. Disparate impact lawsuits do not require proof of intent. Instead, to establish a prima facie case, the plaintiff must provide statistical evidence that a particular minority group is being adversely affected by a specific employment practice. This evidence may come in three different forms:

1. Documenting that pass rates for a decision-making hurdle do not fulfill the *four-fifths rule*. This EEOC rule of thumb states that if the pass rate of a minority group for a particular hurdle is less than 80% of the pass rate for the group with the highest pass rate, the comparative rates are different enough to warrant a conclusion of adverse impact. For example, in *Griggs v. Duke Power Co.* (1971), the plaintiff provided evidence that the organization requirement to complete a cognitive ability test as part of the selection process had a pass rate for White applicants of 58% (the highest pass rate) relative to a pass rate for Black applicants of 6%. The pass rate of the minority group was 10% of the majority group rate, and thus far below the 80% criterion.

2. Providing evidence of a *restricted policy* whereby individuals are excluded on the basis of a required characteristic that is associated with membership in a protected group. For example, instituting a minimum weight requirement of 130 pounds for a given position will disproportionately exclude females, in that females as a population weigh proportionately less than males.

3. Conducting a *workforce utilization analysis* comparing the percentage of minority group members within an organization and within a job to the percentage of minority group members in the relevant labor force for this organization and this job. If protected group members are being consistently screened out, they should be underrepresented in the organization relative to their availability in the labor market.

In response to statistical evidence documenting a disparity, the organization must prove that the employment practice is consistent with business necessity and/or is necessary for the safe operation of

the business. In most cases, this amounts to demonstrating that inferences drawn based on the employment practice are valid in that the practice allows the organization to meaningfully differentiate among individuals on the basis of job-relevant knowledge, skills, or abilities. Should the organization be successful in offering evidence of business necessity, the plaintiff may argue for the substitution of an employment practice that is equally relevant to the job but less discriminatory.

AFFECTIVE EVENTS THEORY

Affective events theory (AET) is a theory of *affect* (the broader term for emotional experiences, including emotion and mood) in the workplace. In addition to focusing on affect, it encompasses cognitions, behavior, attitudes, and other crucial psychological constructs to explain job behavior and performance. The theory primarily builds on the already established cognitive appraisal models and has gathered support from many areas of study in the field of emotions to create a more encompassing theory of work behavior.

Affective events theory proposes that there are two paths to job behaviors, both of which are at least partially influenced by affective reactions to events at work. However, cognitive processes play an essential role in the creation of these reactions. The theory builds on past theoretical successes while also adding

a few new elements (in particular, the notion of time is essential to the model, as well as a more detailed explanation of emotion in the workplace) in explaining job behavior.

ASSUMPTIONS OF AET

Affective events theory makes several assumptions about the workplace and the constructs that describe people's reactions to events that happen there. The first is that job satisfaction is different from affect. Nevertheless, AET also assumes that affect contributes to job satisfaction and can be used to help predict job performance. Related to that, AET assumes that affect influences performance, typically in a detrimental way because emotion is assumed to draw resources from other areas, such as cognitive processing, motivation, and attention, among others.

Another major assumption in the AET framework is that events happen over time, which changes affect continuously. Those events influence a person's immediate affective state but also vary over time as new events arise. Some events are likely to create positive reactions, others negative, and the degree of intensity will also vary from event to event. Because affect is continuously changing within an individual, its influence on behavior is also continuously changing.

THE STRUCTURE OF AET

Affective events theory proposes the following model for predicting workplace behavior. Work environment features (such as office features) precede work events (such as a meeting), and those work events cause affective reactions. Dispositions influence the causal transition from work events to affective reactions, as well as the affective reactions themselves. Those affective reactions then influence affect-driven behaviors, as well as work attitudes. Work attitudes are also influenced by the work environment. Work attitudes in turn influence judgment-driven behaviors.

From that model, one can see that AET proposes two different paths to behavior, both of which are preceded by affective reactions. Affect-driven behaviors stem directly from affective reactions to events in the workplace. Judgment-driven behaviors, on the other hand, are arrived at by a longer route, going from affective reactions to work attitudes (which are also influenced by work environment features) and then to

behavior. However, the starting point for AET is the event. Within AET, an *event* is defined as a change in the environmental circumstances that one is currently experiencing. That change then elicits affect, which then can influence behavior directly (affect-driven behavior) or go through job attitudes to influence behavior indirectly (judgment-driven behavior).

Affect-driven behavior is an almost instantaneous reaction to an event. In many cases, affect-driven responses happen almost immediately after an event occurs. An example might be when, after being yelled at by the boss, an employee quits his or her job without any thought in the heat of the moment. Judgment-driven behaviors, on the other hand, go through a cognitive evaluation via job attitudes. This is a longer process and is usually more deliberate. Referring back to the example, if the employee did not quit immediately but went back to his or her desk and thought briefly about the other components of the job, such as his or her coworkers and the job tasks, and then factored those considerations into his or her decision and reinterpreted the situation, the result would be a judgment-driven behavior. This process might or might not lead the person to quit. The resulting behaviors of affect-driven and judgment-driven processes may not be different, but the decision process is. As the terms themselves imply, affect-driven behavior is primarily influenced by immediate emotional reactions to an event and is typically regarded as a single-step process, whereas judgment-driven behavior is influenced by both emotion and cognition and is regarded as a two-step process that involves a reinterpretation of the original event and the emotion associated with it.

APPRAISAL OF EVENTS LEADING TO BEHAVIORS

Cognitive appraisal theories argue that people strive to make meaning of work events. The meaning of the events then sets the stage for emotional reactions to the event. There are many theories on how people appraise meaning, but the general idea is that every situation has a meaning underlying the event and those meanings are arrived at by a person's interpretations of the situation. Different appraisals of situations lead to different emotions and then behaviors among individuals. Individuals emphasize different appraisal processes when assigning meaning to an event, and that is why individuals can have different emotional reactions to the same situation.

The process of appraising is often regarded as a two-step model. The first step, usually termed *primary appraisal*, includes several mechanisms, but the basic idea is how much an event is congruent or incongruent with one's goals, attitudes, values, and so forth. If an event is seen as congruent, it is assigned a positive value, and if incongruent, the event is viewed negatively. The primary appraisal mechanisms are concerned with whether a stimulus has to do with a person's well-being, which leads to a basic assignment of "good" and "bad" labels. In many instances, the primary appraisals assign enough meaning to the phenomenon to elicit an affective response. Examples of these affective responses can be positive emotions, such as love and relief, but also include negative emotions, such as fright and anxiety. A fuller example with workplace behavior consequences might be one's computer freezing up, which might lead one to hit it out of frustration via primary appraisal, as only a "bad" label has been placed on the event and the reaction is immediate without cognitive factors contributing to the behavior.

Secondary appraisals consist of more cognitively driven processes, such as future expectations or memory, in addition to the primary appraisal. Many emotions occur only when secondary appraisals take place in conjunction with the primary appraisal. An example of a negative emotion that requires both stages is anger. A positive emotion that requires the secondary stage of appraisal is happiness. In both cases (anger and happiness), the emotion is targeted at a specific situation and not a general affective response, as is the case with primary appraisals. In other words, secondary appraisals lead to the assignment of more complex meaning to the event; no longer is the situation just "good" or "bad." Once that greater meaning is assigned to an event, a discrete emotion then emerges that influences one's behavior in conjunction with current job attitudes. So in the example of a computer freezing up, instead of hitting it immediately in a pure affective reaction, the person would pause for a brief moment and the event would be evaluated in two stages, first if the event is good or bad via primary appraisal, and then adding other information to deal with the situation via secondary appraisal. Affective events theory proposes that if job attitudes are positive, one might not hit the computer and would instead take the time to call a technician for help. If attitudes are negative, one might still just hit the computer.

The secondary appraisal process that leads to judgment-driven behavior is more deliberative and requires individuals to take more time (although it could be only a few seconds) to assign the value as compared with primary appraisals and affect-driven behavior. Primary appraisals that lead to affect-driven behaviors are not completely cognition-free, although they are more automatic reactions. However, if the strength of the initial appraisal and the ensuing emotional reaction is robust enough, the primary appraisal and the affect-driven response can last for some time.

For every event, the possible responses of an individual to a given stimuli may initially seem endless, but once a person appraises the situation, the behavior choices become narrowed down based on the person's affective reactions. To date, there is little research on what types of behavior result from the different paths. However, by definition, affect-driven behaviors should be more impulsive and less controlled than judgment-driven behaviors, which consider more factors before a behavior is pursued. Therefore, affect-driven behaviors should disrupt job performance because of their potentially more abrasive social nature, as well as their ability to draw cognitive resources. Judgment-driven behaviors also should reduce job performance, because they reduce time spent on job tasks as well as draw mental resources away from those tasks.

SUMMARY

Affective events theory is a theory of how events in the workplace (in particular, those events that change a person's affect) influence behaviors at work over time. Affect then influences behavior in two possible ways, the first being a direct cause of affect-driven behavior, which is an almost automatic emotional response to an event. The second way behavior is influenced by affect is through its influences on cognitions and attitudes (in addition to the initial affective response), which in turn cause judgment-driven behavior; this is regarded as a more deliberate response to an event or series of events.

AFFECTIVE TRAITS

THE CONCEPT OF AFFECTIVE TRAITS

Trait affect is defined as a tendency to respond to specific classes of stimuli in a predetermined, affect-based manner. Therefore, an affective trait is considered a relatively stable characteristic of personality. There are two general bipolar dimensions of affective responding: trait positive affect (TPA) and trait negative affect (TNA). High TPA is characterized by the tendency to experience positively activated emotions in general, such as excitement, high energy, joy, enthusiasm, and exhilaration. Persons with low TPA have a general tendency to be lethargic, apathetic, and listless, but they do not necessarily experience negative affect. High TNA is defined as the tendency to experience feelings of anger, guilt, fear, annoyance, and nervousness. Low TNA is the other pole of the TNA dimension, characterized by being placid, calm, and contented. The two dimensions, TPA and TNA, are conceptualized as orthogonal or at least separable dimensions, and they show zero to moderate negative correlations with each other. This implies that it is

possible to be simultaneously high or low in both TPA and TNA, high in TPA and low in TNA, and vice versa. Combinations between the extremes are possible, too. The term *affective traits* refers to a person's average level or typical amount of a given emotion, whereas *affective states* are more temporal, situation-bound experiences of moods and emotions.

Both TPA and TNA can be interpreted as the diagonal coordinates in a circumplex model of affect that is built on the orthogonal dimensions of activation and pleasantness. High TPA in this model is a combination of high activation and high pleasantness, and high TNA is a combination of high activation and high unpleasantness.

Whereas TPA has been shown to be robustly related with extraversion, TNA has been similarly linked with neuroticism, two personality factors from the five-factor model of personality (Big Five), although the fit is not perfect. As an explanation, Timothy A. Judge and Randy J. Larsen have developed a model for integrating affect with personality, referring to these relationships. They present evidence that certain personality traits dispose people to be more or less reactive to hedonic stimuli, and they demonstrate that other personality traits indirectly dispose people to modulate their emotional reactions. Extraversion and neuroticism are considered to represent differential sensitivity to typical TPA and TNA stimuli. High-neuroticism individuals are mainly motivated to avoid punishment (negative stimuli), whereas high-extraversion individuals are mainly motivated to gain rewards (positive stimuli).

Affective traits are genuinely individual-level concepts. In a group work context, individual affective traits may combine into a group-level affective tone that in turn is related to experiences and behaviors in the work group.

MEASUREMENT OF AFFECTIVE TRAITS

Several instruments are available for measuring affective traits. The instrument that is most often used is the Positive and Negative Affect Schedule (PANAS), developed by David Watson and his coworkers. It comprises two 10-item scales, one for assessing positive and one for assessing negative affect. The items refer to the high-activation aspect of negative and positive affectivity, respectively. Because the PANAS scales lack low-activation markers of negative and positive

affect, they sample only a limited part of the affect circumplex. The PANAS shows good reliability and high discriminant validity with low intercorrelations between the positive and negative affectivity scales.

In addition to direct measures of affective traits such as the PANAS, researchers use personality measures, particularly neuroticism and extraversion scales, for assessing TNA and TPA, respectively.

AFFECTIVE TRAITS AND JOB SATISFACTION

Affective dispositions influence the extent to which people are satisfied with their jobs. A recent meta-analysis conducted by Carl J. Thoresen and his associates extracted an estimated mean population correlation of $\rho = .33$ between TPA and job satisfaction and of $\rho = -.37$ between TNA and job satisfaction. Those correlations indicate a rather modest but nevertheless substantial relationship between trait affectivity and job satisfaction. There is also evidence from longitudinal studies for a predictive value of TPA and TNA for several aspects of job satisfaction up to 2 years later, as well as correlations of dispositional affect in younger years with job satisfaction in older years.

The underlying processes through which trait affectivity influences job satisfaction are not well understood. Most studies concerned with trait affectivity and job satisfaction are correlation studies and do not allow one to test for causality. Research has concentrated on TNA rather than TPA. Because high-TNA individuals are more sensitive to negative stimuli, they are likely to react more negatively when experiencing negative job events, which consequently lowers job satisfaction. Furthermore, it is possible that high-TNA individuals have a higher threshold for positive stimuli and therefore react with a lower magnitude to positive events. They may experience the effects of positive mood-inducing events to a lower extent or for shorter periods of time than do low-TNA individuals. There is some evidence for the assumption that TPA represents reward-signal sensitivity and TNA represents punishment-signal sensitivity. For example, TPA is related to pay satisfaction (i.e., a salient reward), but TNA is not. Additionally, TNA individuals may dwell on their failures and those of others, thus causing negative interpersonal interactions with their peers and superiors and lower job satisfaction.

AFFECTIVE TRAITS AND JOB PERFORMANCE

Potential relationships between affective traits and job performance have been discussed in the context of the *happy-productive worker hypothesis* and the *power of being positive*. By drawing on expectancy theory, some researches have argued that individuals high on TPA should show higher task performance because of their positive expectations about the relationship between effort and performance and between performance and positive outcomes. In addition, it has been suggested that TPA should lead to higher goals and more persistence in the face of obstacles. Moreover, researchers have proposed that TPA is associated with extra-role and citizenship behaviors, whereas TNA impedes supportive social interactions.

Although there are many studies on the relationship between trait affect and job satisfaction, far fewer empirical studies have examined the relationship between affective traits and job performance. Studies that used rather broad well-being measures as indicators for affective traits found positive relationships between an individual's tendency to experience and show positive affect at work and supervisory rating of job performance, also when using longitudinal designs. Managers experiencing higher levels of well-being and positive affect showed higher decision-making accuracy, higher interpersonal performance, and higher managerial performance. In contrast, most studies that used the PANAS to assess trait affect failed to find significant bivariate relationships between TNA or TPA and task performance. Trait affect has been shown to be empirically related to extra-role performance at the individual level (e.g., coworker support and work facilitation) and to prosocial behavior and cooperativeness at the group level.

It has been suggested that individual core self-evaluations play an important role for organizational behavior. Core self-evaluations comprise self-esteem, generalized self-efficacy, emotional stability (i.e., low neuroticism), and locus of control. Although these core self-evaluations are not affective traits in a narrow sense, findings on the relationship between emotional stability and job performance are relevant here, because the emotional stability construct largely overlaps with TNA. Meta-analytical evidence suggests that emotional stability as an aspect of core self-evaluations shows a weak positive correlation with job performance.

In addition, meta-analyses on the relationship between personality factors and job performance shed some light on the relationship between affective traits and job performance. Neuroticism shows a negative relationship with various facets of job performance, with most true-score correlations not exceeding $\rho = -.20$. Extraversion is positively related to job performance, with most true-score correlations staying in the range between $\rho = .10$ and $\rho = .20$.

AFFECTIVE TRAITS AND THE STRESSOR-STRAIN RELATIONSHIP

Affective traits, particularly TNA, are related to perceptions of job stressors and strains, with individuals high on TNA reporting higher levels of job stressors and strains. These relationships imply that the observed correlation between self-reported job stressors and strains may be partially caused by TNA. Therefore, it has been suggested that researchers should statistically control for TNA when analyzing relationships between self-reported job stressors and strain. However, this view has been challenged in a lively debate in which it has been argued that TNA plays a substantive role in the stressor-strain relationship.

CONCLUSION

There is broad empirical evidence that affective traits are related to job satisfaction. However, the processes underlying this relationship need further research attention. Although well-being measures were found to be related to job performance, the empirical relationships between affective traits and related personality concepts, on the one hand, and task performance, on the other hand, are weak. Affective traits, however, seem to be more relevant for contextual performance. Therefore, one might assume that group or organizational performance benefits more from TPA than does individual job performance.

AFFIRMATIVE ACTION

Affirmative action has been one of the most controversial public policies of the past 40 years. A conceptual definition of *affirmative action* is any measure, beyond a simple termination of discriminatory practice, adopted to correct for past or present discrimination or to prevent discrimination from recurring in the future. In practice, organizational affirmative action programs (AAPs) can and do encompass a multitude of actions. These actions are shaped by federal, state, and local laws and regulations. Although some educational institutions apply affirmative action to student admissions and many countries have corresponding laws and regulations, this entry is limited to workplace affirmative action in the United States.

LEGAL ISSUES

Affirmative action law in the United States is jointly determined by the Constitution, legislative acts, executive orders, and court decisions. It is complex, incomplete, and open to revision. The Office of Federal Contract Compliance Programs is responsible for developing and enforcing most AAPs, although the Equal Opportunity Employment Commission (EEOC) enforces AAPs in the federal sector.

A distinction exists between so-called set-aside AAPs and organization-specific AAPs. *Set-aside* AAPs exist when a public organization (e.g., a municipality or federal agency) is required to set a goal for directing a certain percentage of its budget to qualified firms—typically those owned by members of an underrepresented group.

In contrast, *organization-specific* AAPs are created for one of three reasons. First, some organizations are required by a court order or an EEOC consent decree to establish an AAP to compensate for illegal discrimination. These AAPs are relatively rare. Second, many organizations establish AAPs to satisfy regulatory requirements. Specifically, the Rehabilitation Act of 1973 and the Vietnam Era Veterans' Readjustment Assistance Act of 1974 require certain federal contractors to take affirmative action to employ individuals with disabilities and certain veterans, respectively. Most important, Executive Order 11246, signed by President Lyndon Johnson in 1965 and subsequently amended, requires federal contractors to take affirmative action to eliminate discrimination on the basis of race, color, religion, sex, or national origin. Along the same lines, state and local laws and regulations may require organizations to take affirmative action to improve the employment opportunities of various groups. Third, some organizations establish AAPs on a fully voluntary basis.

Precisely which organizations are required to establish AAPs and which actions are required, permitted, or forbidden varies with the legal basis for the AAP. Furthermore, actions of state and federal governments are limited by the U.S. Constitution, whereas actions of firms in the private sector are constrained by state and federal legislation (e.g., the Civil Rights Acts of 1964 and 1991). The following brief and incomplete description focuses on affirmative action as required by Executive Order 11246, because that is the primary source of AAPs in the United States and is the basis of much of the controversy.

Organizations with annual federal contracts of at least \$10,000 are required to take affirmative action to eliminate discrimination on the basis of race, color, religion, sex, or national origin. They must establish nondiscrimination policies and communicate those policies to employees and applicants. Organizations with at least 50 employees and contracts above \$50,000 are further required to perform and report the results of utilization analyses in which they compare the gender and racial distributions of their workforce to the

relevant labor markets. The relevant labor market for any position includes only those individuals who are qualified for that position and who reside in the recruitment area. If the utilization analysis reveals that all groups are reasonably represented, no further actions are required. If the utilization analysis reveals that any group defined by gender, race, or ethnicity is underrepresented, the firm must establish flexible goals to eliminate the underutilization and must make a good faith effort (i.e., take affirmative actions) to meet those goals. Utilization analyses are not required for other protected dimensions (i.e., disability, veteran status, religion), so it is impossible to determine whether underrepresentation exists along these dimensions.

An important question is which actions are permitted when underutilization is revealed. Federal regulations strongly emphasize nonpreferential actions such as the elimination of barriers and the use of targeted recruitment or training. Because these approaches may fail to eliminate substantial underrepresentation, some organizations may want to take stronger actions. In so doing, the firm must not violate the constraints established by the Constitution and antidiscrimination law. It is clearly illegal to use quotas or to give preferences to unqualified members of the underrepresented group (e.g., through race norming of the selection test). Furthermore, Supreme Court decisions have determined that any AAP that gives a positive weight to racial minority status is subject to "strict scrutiny." Such an AAP must be remedial, narrowly tailored, and temporary; must not trammel the rights of others; and must further a compelling governmental interest. Note that the final requirement can be satisfied only within the public sector. Although it has been suggested that private-sector organizations might use the economic value of diversity to justify positive weighting of racial minority status, it is not clear that such an argument would be approved by the Supreme Court. Although positive weighting of gender requires only intermediate scrutiny rather than strict scrutiny, it would still be a risky approach.

EMPIRICAL RESEARCH

As mentioned previously, affirmative action is a controversial public policy. The debate regarding whether it should be eliminated, perpetuated, or expanded is complex. For example, philosophical arguments have been offered regarding the appropriateness of using race-conscious approaches to attain a race-blind

society. These arguments tend to focus on race-based affirmative action and occasionally gender-based plans; they rarely mention policies that target veterans or individuals with disabilities. These debates also focus on preferential forms of affirmative action rather than the more common, and legal, nonpreferential forms. Empirical research, in contrast, has focused on the consequences of affirmative action and on predictors of attitudes toward affirmative action.

CONSEQUENCES OF AFFIRMATIVE ACTION

For Organizations

A logical analysis shows that affirmative action could either help or hurt organizational performance, depending on details of the AAP and on the procedures used by the organization in the absence of affirmative action. Positive effects should occur if the AAP increases the organization's access to the labor market (e.g., through intensive recruitment) or decreases discrimination against women or racial or ethnic minorities. Negative effects should occur if the organization uses a preferential AAP that supplants a nondiscriminatory procedure. In addition, organizations must bear the costs of administering AAPs. Consistent with the logical uncertainty, empirical research has failed to demonstrate any substantial effect of affirmative action on organizational performance.

For Target Groups

A different line of research has assessed the economic impact of affirmative action on the targeted groups. Affirmative action appears to have improved employment outcomes of targeted groups, but the effects have varied in complex ways depending on factors such as the targeted group, geographic region, time period, and type of position. For example, affirmative action had a substantial positive impact on African Americans in the South between 1965 and 1975, presumably because that time and place offered a substantial opportunity for improvement. On the other hand, affirmative action had virtually little or no effect during the 1980s, perhaps because the Reagan administration decreased support for the regulatory agencies and substantially revised those agencies' policies and procedures. Little or no research exists on the effects of affirmative action on employment of individuals with disabilities or veterans. Because

organizations are not required to report employment statistics of these groups, such effects would be difficult to document.

There is also some evidence that affirmative action may lead to stigmatization of individuals who belong to the AAP target group. The logic is consistent with the discounting principle of attribution theory. When targeted individuals are selected in the context of an AAP, others are uncertain about whether their selection was because of their performance or the AAP. In the absence of affirmative action, this uncertainty disappears and the individual is assumed competent. Research reveals such stigmatization when observers believe or are told that the AAP involves preferences. It can be eliminated or greatly reduced by providing compelling evidence that the AAP is nonpreferential or that the selected individual is fully qualified or has performed well.

A related stream of research deals with self-stigmatization by target group members. According to the logic outlined above, members of AAP target groups may doubt their own competence and consequently lose confidence and interest in the job. Although this effect has been observed, almost all supportive evidence has come from laboratory research in which White female college students are explicitly told that they have been preferentially selected on the basis of their gender. There is little evidence for this effect among racial or ethnic minorities, and the effect is absent or much smaller when participants are given clear evidence of their competence or are told their selection was based in part on merit.

For White Males

A final question concerns the impact of affirmative action on White males. Although there are many reports of *backlash*—opposition by White males based in part on the belief that they have been hurt by affirmative action—there is surprisingly little research on this question. Logically, the effect should be negative if affirmative action reverses traditional biases that favor White males or if preferential forms of affirmative action replace nondiscriminatory procedures. The limited research that exists reveals such a negative effect. Of course, this assumes a “fixed pie” situation; if implementation of an AAP enhances organizational performance because of the increased diversity, that increased performance may help all organization members.

Attitudes

Perhaps the largest body of empirical research on affirmative action has dealt with public attitudes toward the policy. This work has assessed the effects of structural predictors, perceiver variables, and psychological mediators of the effects.

The structural predictor that has received the most attention is AAP strength—the weight given by the AAP to demographic characteristics. Specifically, the public strongly supports AAPs that require only the elimination of discrimination. Support decreases somewhat for AAPs that are designed to enhance target group opportunities—for example, by requiring targeted recruitment. There is a further drop in support if the AAP requires selection of underrepresented group members when their qualifications are equivalent to those of other applicants. Note that such an AAP would rarely if ever pass legal muster. Finally, there is strong opposition to AAPs that require preferential selection of underrepresented group members even when their qualifications are inferior to those of other applicants. Although such an AAP would be illegal, many scholars who study attitudes toward affirmative action attitudes have described it in those terms, and many people believe preferences are common. Indeed, although most research on AAP strength has involved manipulation of the AAP, research on public beliefs reveals corresponding effects, so that individuals who believe affirmative action merely requires the elimination of discrimination have more positive attitudes than those who believe it involves preferences.

The only other structural predictor that has received enough attention to merit conclusions is the identity of the target group. It appears that attitudes, at least of White respondents, are more negative when the AAP is described as targeting African Americans or minorities than when it is said to target women or individuals with disabilities.

The two perceiver variables that have received the most attention are respondent race and gender. In general, African Americans report the strongest support for affirmative action and Whites the strongest opposition, with Hispanics and Asians reporting intermediate levels of support. However, this race effect is moderated by AAP strength, increasing in size as the AAP gives greater weight to demographic status. The effect of gender on attitudes is much smaller, but in general, women report more support than do men.

Attitudes are also associated with several opinion variables. Most significantly, opposition increases with the respondent's racial prejudice and sexism. In addition, those who subscribe to a conservative political ideology or who identify with the Republican Party report greater opposition than do those who are politically liberal or who identify with the Democratic Party. Opposition also increases with the level of the respondent's *social dominance orientation*—an individual difference variable that represents a general opposition to equality and support for group-based dominance. Finally, support for affirmative action is associated with the belief that the target group experiences discrimination and thus that affirmative action is needed.

Research on psychological mediators finds that support for affirmative action is positively associated with anticipated positive effects of the AAP on the respondent's personal self-interest and on the respondent's demographic group. But the strongest association of all is with perceived fairness of the AAP—people support AAPs they consider fair and oppose those they consider unfair. As this would suggest, providing a justification increases support for affirmative action, but only if the justification refers to the value of diversity or the need to make up for past discrimination; simply citing underrepresentation typically decreases support instead of increasing it.

AGE DISCRIMINATION IN EMPLOYMENT ACT

The Age Discrimination in Employment Act (ADEA) of 1967 (amended in 1986) is a U.S. federal law that prohibits discrimination in employment against individuals who are at least 40 years old. It was enacted by the Congress to promote the employment of older people based on their ability and to prevent intentional and nonintentional forms of age discrimination. The act applies to private, public, and foreign companies with more than 20 workers located in the United States, as well as to unions and employment agencies.

PROHIBITED PRACTICES

The ADEA makes it unlawful to discriminate against a person because of his or her age “with respect to any term, condition, or privilege of employment.” That prohibition applies to such things as hiring, firing, job assignments, promotions, training opportunities, discipline, and employee compensation. The ADEA covers individuals age 40 and above; a worker who is 39 years old at the time of the alleged discrimination is not entitled to ADEA protection. The ADEA also prohibits employer discrimination *among* older workers. For example, an employer cannot hire a 50-year-old over a 60-year-old simply because of age.

Although the ADEA restricts the use of age by employers, it allows age to be taken into account in some situations. For example, in recognition of the

fact that benefits costs may be higher for older workers, the ADEA allows employers to provide different benefits to older and younger workers if the amount spent on benefits received by older and younger workers is the same. The ADEA also recognizes several general defenses that may provide a legal justification for policies or practices that adversely affect older workers, as discussed in the following section.

ESTABLISHING AND DEFENDING ADEA CLAIMS

Violations of the ADEA may be established using either the disparate treatment or disparate impact theories of discrimination. The legal defenses that are relevant and potentially available to an employer depend on which theory of discrimination the plaintiff relies on.

Disparate Treatment

The disparate treatment theory of age discrimination, or *intentional* age discrimination, requires plaintiffs (job applicants or employees) to prove that the employer used age as a factor in an employment decision or action. Examples include the refusal to hire older workers based on stereotypes about their limited capabilities and excluding older workers from certain types of training.

In cases where it is established that the employer has a policy or practice that treats individuals differently based on age, the employer must prove that the age standard it used is a *bona fide occupational qualification* (BFOQ) for the job in question to avoid a finding of illegal discrimination. The BFOQ defense is narrowly construed and difficult to establish. The employer must prove that age is directly related to the ability to perform an important aspect of the job that goes to the essence of the employer’s business. It is not enough to merely show that younger workers tend to perform better on the job; it must be shown that substantially all persons over the age limit cannot successfully perform the job, or that it is highly impractical to assess the relevant ability on an individual basis. Age-based BFOQs are most commonly supported in jobs directly involving public transportation or safety, for which there is credible evidence that abilities essential to the job diminish significantly with age.

In the more typical case, where there is not an explicit age-based policy or practice and the employer denies that age played any role in the challenged

employment action, the plaintiff must make an initial showing of intentional age discrimination using either *direct* evidence (e.g., help-wanted advertising indicating age preferences, disparaging age-related comments) or *circumstantial* evidence. To establish a prima facie case of disparate treatment using circumstantial evidence in a refusal-to-hire case, the plaintiff must show that (a) she or he is a member of the protected age class; (b) she or he was qualified for the position in question; (c) she or he was denied the position; and (d) someone significantly younger, with similar or lesser qualifications, received the position she or he was denied.

If the plaintiff establishes the foregoing, the employer must rebut the circumstantial evidence of intentional discrimination by producing evidence that it had a legitimate, nondiscriminatory explanation for its action (e.g., poor job performance, good faith belief that someone else was more qualified). If the employer is able to provide such a reason, then the burden shifts back to the plaintiff to show that the reason offered by the defendant is a pretext for discrimination.

Disparate Impact

Disparate impact age discrimination claims involve employer policies or practices that appear neutral on their face but that have a substantially greater negative impact on older individuals when put into effect. For example, in several cases, the employer's use of what appeared to be age-neutral physical fitness requirements in hiring decisions were found to have a substantially greater impact in screening out older employees.

Even if a plaintiff meets his or her burden of identifying a specific employer policy or practice that adversely affects older workers, the employer may still prevail if it can show that its policy or practice involves a *reasonable factor other than age* (RFOA). The RFOA defense, unique to the ADEA, requires the employer to demonstrate that there is a good or rational business reason for the employer policy or practice. The RFOA defense requires a standard of justification that is significantly lower than the BFOQ defense (i.e., an RFOA is much easier to establish) and somewhat higher than the legitimate nondiscriminatory reason showing that will rebut a circumstantial prima facie case of disparate treatment. Evidence that the challenged policy or practice is related to job

performance would be sufficient, but it may not be necessary. For example, in a 2005 ruling (*Smith v. City of Jackson, Mississippi*, the Supreme Court held that the employer's perceived need to offer junior police officers salaries that were competitive in the job market was an RFOA that justified an employer policy that adversely affected older officers.

REMEDIES FOR ADEA VIOLATIONS

A range of remedies are potentially available to successful plaintiffs in ADEA cases, including reinstatement to their old job, employment, back pay, front pay, promotion, and court costs. In addition, if it is shown that the employer knew that its actions violated the ADEA or showed reckless disregard for whether its actions violated the act, then the court has discretion to award liquidated damages equal to double the amount the plaintiff is otherwise owed. Noncompensatory damages (e.g., pain and suffering) are not available.

IMPACT OF THE ADEA

Without question, the ADEA has increased U.S. employers' awareness of and sensitivity to the use of job applicant and employee age in employment decisions. Some provisions of the ADEA have had a direct and manifest impact on employer practices. For example, the 1986 amendment to the ADEA has eliminated the use of once common age-based mandatory retirement policies for all but a relatively narrow group of employees (high-level executives and employees in selected occupations in which age is a BFOQ). The continued dramatic growth in the number of lawsuits alleging ADEA claims suggests that older workers have also become more aware and less tolerant of age-based employment discrimination. Research investigating the impact of the ADEA suggests that although evidence of differential treatment based on age can still be found in the American workplace, overall, the ADEA has had a positive impact on the employment prospects of older workers. More specifically, empirical evidence indicates that the ADEA helped boost the employment levels of older workers, particularly those aged 60 and over.

AMERICAN PSYCHOLOGICAL ASSOCIATION, ASSOCIATION FOR PSYCHOLOGICAL SCIENCE

The two primary professional psychological associations in the United States are the American Psychological Association (APA) and the Association for Psychological Science (APS; formerly called the American Psychological Society).

AMERICAN PSYCHOLOGICAL ASSOCIATION (APA)

Description of APA

The American Psychological Association was founded in 1892 as a scientific and professional membership organization for the field of psychology in the United States. Headquartered in Washington, D.C., APA comprises 53 divisions, covering the spectrum of psychological specialties (e.g., clinical, experimental, developmental, educational, personality, and social). The association is a corporation governed by a six-member board of directors and a council of representatives. Many of the organization's tasks are carried out by boards and committees.

APA Membership

With more than 150,000 members, APA is the largest psychological association in the world. Membership categories include (a) member (i.e.,

doctorate in psychology from an accredited institution); (b) student affiliate (programs for graduate, undergraduate, and high school students); (c) teacher affiliate (community college or high school teachers); (d) international affiliate (psychologists who live outside the United States and Canada); and (e) fellow (elected status; members who have demonstrated unusual and outstanding contributions or performance in psychology on a national level).

Mission of APA

The mission of APA is to advance psychology as a science and profession and as a means of promoting health, education, and human welfare. Five mechanisms are used to accomplish this mission: (a) broadly and liberally encouraging all of the psychological disciplines (specialty areas); (b) promoting psychological research and improving the methods and manner in which these studies are conducted; (c) improving the qualifications and value of psychologists by maintaining high standards for professional conduct, ethics, education, and achievement; (d) maintaining the utmost standards for professional ethics and conduct of members of APA; and (e) increasing and spreading knowledge of psychology through a variety of methods (e.g., meetings, publications, networking, and discussions).

Functions of APA

The association sponsors services to advance the education and practice of psychology, including continuing education workshops, an annual convention, and an awards program. Publications of APA include a monthly news magazine (*Monitor on Psychology*); specialized newsletters; division newsletters; hundreds of books; more than 40 journals; videos; practice-related pamphlets; and the largest online research database for psychological information in the world (PsycINFO, PsycARTICLES). A major function of APA is to advise decision makers in Congress on a diverse range of legislative and regulatory issues (e.g., aging, crime, terrorism, substance abuse).

ASSOCIATION FOR PSYCHOLOGICAL SCIENCE

Formation of APS in Relation to APA

During the 1970s, many members of APA grew discontented with the association's primary focus on

issues pertaining to clinical practice (e.g., health care). This focus led many members to believe that their needs and interests as scientific and academic psychologists were not being met. Proposals submitted to make APA the primary association for scientific psychologists were not approved by the membership. Consequently, in August 1988, the American Psychological Society (APS) was formed to advance psychology as a scientifically oriented discipline. In January of 2006, APS officially changed its name to the Association for Psychological Science to better reflect its core mission and values.

Description of APS

The Association for Psychological Science is a national nonprofit membership organization governed by an 11-member board of directors, representing different fields of psychology. In contrast to APA, APS is not divided into specialty areas; rather, it considers the scientific field of psychology as a whole.

APS Membership

There are more than 14,000 members of APS, including academics, researchers, clinicians, teachers, and administrators. Membership types include (a) member (i.e., doctoral degree in psychology or a related field, or sustained contributions to scientific psychology); (b) retired; and (c) student affiliate (graduate, undergraduate). The association also offers other categories of membership, which have reduced membership rates (e.g., first-year PhD, postdoctorates).

Mission of APS

The mission of APS is to promote, protect, and advance the interests of scientifically oriented psychology in research, application, teaching, and the improvement of human welfare.

Functions of APS

The association publishes a newsletter and three journals: *Psychological Science*, *Current Directions in Psychological Science*, and *Psychological Science in the Public Interest*. Each year, APS sponsors a professional conference. In addition, APS honors particularly notable contributors to the field by awarding them fellow status and through specific achievement

awards. Further, APS has been actively involved in obtaining legislative and federal support for scientific psychological research (e.g., increasing visibility for health and behavioral research within agencies such as the National Institutes of Health).

AMERICANS WITH DISABILITIES ACT

In 1990, Congress passed the Americans With Disabilities Act (ADA) to provide equal protection under the law to disabled citizens, who are not identified in the Civil Rights Acts of 1964 or 1991 as a protected group. The ADA covered various aspects of daily life for the disabled, which are addressed under the following titles:

Title I: Employment

Title II: Public Services

Title III: Public Accommodations

Title IV: Telecommunications

Title V: Miscellaneous Provisions

This entry considers only Title I, on employment.

Title I of the ADA was intended to strengthen the existing Rehabilitation Act (RA) of 1973 by making language more specific and by including private-sector

employers under the previous umbrella of the RA. It provided standards for enforcement of the law and charged government with the responsibility for enforcement. The ADA is administered by three different agencies: the Department of Justice, for public-sector employees; the Equal Employment Opportunity Commission (EEOC), for private-sector employees; and the Department of Transportation, for nonfederal sectors affecting commerce. Although originally covering only employers with 25 or more employees, the act was amended in 1994 to apply to all businesses with 15 or more employees.

Statistics from the EEOC demonstrate that the rights of the disabled are being increasingly defended through litigation. In 1992, ADA claims represented less than 2% of all claims filed with EEOC. From 1993 through 2003, these claims have averaged approximately 20% of all claims filed with EEOC. To put this figure in context, the respective figure for claims alleging discrimination on the basis of race or color is 36%; on the basis of sex, 31%; and on the basis of age, 21%. In the year 2003 alone, ADA claims filed through EEOC resulted in total benefits to disabled claimants of \$45.3 million. An ADA claim typically consists of an individual's assertion that he or she is disabled, had the necessary qualifications for the job in question, and was denied an accommodation that would have made it possible to successfully perform the job, or at least the essential functions of that job. The issues of accommodations and essential function are discussed below.

Although race, sex, and age are relatively clear attributes allowing for a simple determination of who is covered, the disability statute is not so easily applied. Since the passage of ADA, the U.S. Supreme Court has heard 11 cases involving it, many of them dealing exactly with issues related to who is covered by the act. The determination of who is a member of the class of disabled depends on several statutory definitions. A person may be classified as disabled if (a) he or she has a current mental or physical impairment that limits a major life activity, (b) can demonstrate a history of such an impairment, or (c) can show that he or she is being treated as if he or she has, or is perceived to have, such an impairment. But for an individual's claim to be covered by the ADA, it is not sufficient to simply demonstrate that he or she has an impairment. This impairment must be shown to substantially limit a major life activity. Major life activities include obvious categories such as self-care,

walking, talking, seeing, hearing, and breathing. But often, the category is not so obvious, and the individual may claim that the limited life activity is actually that of working. When this is the case, the claimant must show not merely that he or she is unable to perform a single job but that he or she cannot perform successfully in a broad range of jobs as a result of the disability. An example from a court case provides an example of the requirement. An individual with a fear of heights is not seen as substantially limited simply because he or she cannot work on the upper floors of a building, because a wide variety of other jobs are available from other employers that do not require employees to work in high locations.

In addition to showing that they are disabled using any of the definitions above, claimants must also demonstrate that they are qualified. It is not sufficient for claimants simply to show that they *possess* the knowledge, skills, or abilities needed to do the job. Rather, to meet this requirement, a claimant must show that he or she has the knowledge, skills, and abilities to *perform* essential job functions and can successfully perform those essential functions with or without a reasonable accommodation. Both of these conditions must be met before the court will consider any claims of discrimination on the part of the employer. If the person is not considered disabled (with the added qualification that the disability substantially limits a major life activity) or does not possess the necessary qualifications to perform essential functions of the job, then the case is dismissed.

In a general sense, essential functions define why the job exists. For example, the essential functions of a bus or train driver are to guide a vehicle on a prescribed route within a fixed period of time and to pick up and discharge passengers. Essential functions of a firefighter are to suppress fires while protecting lives and property. Essential functions are usually identified through the completion of a job analysis or the examination of a job description that resulted from a job analysis. Since 1990, many job analyses have identified certain functions as essential to comply with ADA requirements. Various courts have ruled that to meet the burden of showing that one can perform the essential functions of a job, a claimant must show that he or she can perform *all* of the essential functions with or without an accommodation, not merely some of them. This logic also affects the very definition of what a job is. Claimants have often argued that they could perform a job if some of the essential functions

were moved to other jobs. Courts have held that the employer is not required to redefine a job for purposes of accommodating a disabled applicant or employee. On the other hand, the employer cannot exclude a disabled applicant or employee from a job because the disabled individual cannot perform a *nonessential* function. As an example, a recent amputee who had been a former patrol officer could ask to be placed on desk duty in a police precinct. The department might argue that even desk officers may be required to respond to outside events in an emergency; however, if it could be shown that no such emergency had ever occurred, then the hypothetical essential function of the desk-duty officer to respond to outside emergencies would be seen as nonessential.

Drug and alcohol abuse occupy special status in ADA. Only rehabilitated drug abusers are protected; individuals currently using illegal substances (e.g., heroin, cocaine, marijuana) are not. The act permits drug testing of employees, including former addicts, provided these tests are reasonable. In this context, *reasonable* means an articulated policy that is nondiscriminatory. For example, a drug testing policy specifying that testing will occur after a workplace accident or as part of a return-to-work determination after an injury would be seen as nondiscriminatory. In contrast to those using illegal drugs, those who might be defined as current alcoholics may be covered by the ADA and may request accommodations. However, alcohol abusers are held to the same standard as any other employee with regard to not consuming alcohol at the work site and not being under the influence of alcohol when reporting to work. In these instances, alcoholism is not protected as a disability. Nevertheless, an employer may not take adverse employment action against an alcoholic employee because of the consumption of alcohol during nonwork hours unless the consumption has resulted in behavior (e.g., DUI or assault on coworkers during nonwork interactions) that would have led to dismissal or suspension for any other employee who engaged in similar activities. Appropriate accommodations for alcoholic employees might include (a) making sure the employee knows about available counseling, (b) asking the employee to make a commitment to rehabilitation, understanding that failure to honor this commitment might result in termination, (c) establishing a ladder of progressive discipline (e.g., verbal warning → written warning → suspension → termination) for those who continue to drink while in an outpatient

treatment program, and (d) providing the opportunity for inpatient treatment if outpatient treatment is unsuccessful.

Those individuals diagnosed with AIDS and other infectious diseases are also protected by ADA, to the extent that the condition does not pose a direct threat to the health and safety of other individuals. As examples, an HIV-positive surgical nurse who refuses to transfer to a nonsurgical area is not protected by the ADA from involuntary reassignment or termination. In contrast, a hospital clerical worker who is HIV-positive cannot be excluded from that position as a result of some general and nonspecific fear that the disease might be transmitted to patients or coworkers. These examples help to demonstrate the more general principle of context. Diabetics and epileptics might function fine in certain job contexts (e.g., routine office work) yet be considered threats to the health and safety of others in other contexts (e.g., jobs involving the use of heavy machinery or working in sensitive positions in air traffic control or nuclear power).

The reasonable accommodation requirement of ADA is unique. It means that the employer may be required to make modifications of the application process, the work environment, and/or the way in which the job functions are performed. It is assumed that there will be a dialogue between the employer and the disabled applicant or employee that will identify what might be considered a reasonable accommodation for the disabled individual. As an example, individuals who are visually impaired may request an oral assessment or someone to read test questions and possible answers to them. Such individuals, if hired, may request a modified work environment to offer protection from moving equipment. Finally, they may request various technical devices (e.g., voice recognition equipment, high-power lighting, or magnification) to enable successful completion of essential job functions. Such accommodations must be reasonable and entail looking at various characteristics of the employing organization, including the cost of the accommodation, the financial resources available for such an accommodation, and the effect of such an accommodation on the overall capability of the organization to conduct business.

The ADA also has practical implications for the application and employment process. Individuals may not be asked to disclose information about a disability (other than a request by that individual for an accommodation in the application process) until *after* an offer

of employment has been made. This is to prevent individuals from being unfairly discriminated against as a result of a covered disability during the employment screening process. The most obvious point at which to run afoul of this protection is the preemployment physical. Although it is permissible to give a preemployment physical to any individual (including disabled applicants), it cannot be administered *before* a conditional offer of employment has been given to successful applicants. A conditional offer is one that is contingent on passing a physical examination. Further, such physicals must be administered to all applicants, not simply to those who appear to be disabled or who have asked for an accommodation. Even at early stages of the application process—before a conditional offer of employment is made—an employer is permitted to ask individuals if they think that they can perform essential functions that are described to them. Asking applicants to undergo testing for illegal drug and alcohol use as part of the application process does not violate the provisions of the ADA.

W. F. Cascio, in 2005, suggested several ways in which employers may embrace the spirit of ADA. These include the following:

- Making the workplace more accessible to individuals with various physical impairments by installing ramps for individuals in wheelchairs or with visual impairments and installing TTY (teletypewriter) and voice amplifiers for individuals with hearing impairments. Newly designed keyboards and computers have been developed for quadriplegics and individuals with cerebral palsy.
- Creating a position within the equal employment opportunity domain of an organization for an individual who would focus on disability issues. Such a position would include responsibility for the orientation and socialization of newly hired disabled workers. This orientation would include the supervisors and coworkers of the disabled employee.
- Educating senior managers in disability issues and gaining commitment to recruit, select, and accommodate individuals with disabilities when necessary.
- Analyzing jobs with the specific aim of identifying tasks and functions for which various disabilities are not an impediment to successful performance.
- Describing successful accommodation experiences to the employees within the organization as well as to those outside of the organization.

The ADA is a complex statute that is still evolving. It was written in a way that encouraged cooperation

and dialogue between an employer and a disabled applicant or employee. The courts look favorably on evidence of good faith efforts by both parties to work out a reasonable accommodation where possible. It is best for neither the applicant/employee nor the employer to forget the importance of this dialogue in an eventual judicial decision, should such a decision become necessary.

APPLICANT/TEST-TAKER REACTIONS

The term *applicant reactions* is used to refer to an applicant's affect, attitudes, and cognitions toward a selection process. Applicant reaction models suggest that reactions are very complex and involve perceptions of multiple aspects of specific tests and the testing process in general. Stephen Gilliland was one of the first researchers to put forth a theoretical model of applicant reactions, and this model has guided much of this research over the past decade. Gilliland's model is based on theories of organizational justice. Organizational justice is concerned with the fairness of the distribution of organizational outcomes (outcome fairness) and the fairness of procedures used to distribute these outcomes (procedural justice). Gilliland adapted the basic principles of organizational justice to provide a comprehensive model of how applicants perceive and react to selection procedures. This model has received considerable support.

Gilliland's model suggests that selection systems and tests are viewed favorably by applicants

(i.e., are considered fair) to the extent they comply with or violate procedural and distributive justice rules. These procedural and distributive justice rules are standards that applicants hold for how they expect to be treated and how selection procedures should be administered and used. These justice rules determine perceptions of process and outcome fairness, such that when the rules are satisfied, the selection process and outcome are perceived as fair, but when they are violated, the selection process and outcome are perceived as unfair. As will be discussed, applicant perceptions of the fairness of a selection process can influence a number of important individual and organizational outcomes. It should be noted that according to Gilliland's model, justice rules would not directly relate to applicant intentions or behavior, but would do so indirectly through process fairness perceptions. For example, perceived job relatedness is an example of a procedural justice rule. *Perceived job relatedness* refers to the extent to which the applicant perceives that the content of a test reflects the content of the job (e.g., the knowledge, skills, and abilities required by the job). Perceived job relatedness has been recognized as the most important procedural justice rule because it consistently influences fairness perceptions and, through fairness perceptions, test performance.

Over the years, several researchers have modified and expanded Gilliland's original applicant reactions model to include a number of additional antecedents and moderator variables. For example, Ann-Marie Ryan and Robert Ployhart revised the Gilliland model and included an applicant's affective and cognitive states during the selection processes, as well as general perceptions about testing and selection, as important in understanding antecedents and consequences of applicant reactions.

JUSTICE RULES

In applicant reaction models, procedural and distributive justice rules are important antecedents of fairness perceptions. Although a number of procedural and distributive justice rules exist, Gilliland specified 10 procedural and 3 distributive justice rules, and these have received research attention:

Procedural Justice Rules

1. *Job-relatedness*. The extent to which a test appears to measure content relevant for the job

2. *Opportunity to perform*. The extent to which applicants perceive that the test or test process allows them the opportunity to express themselves prior to a selection decision
3. *Reconsideration opportunity*. The opportunity to challenge or modify the decision-making process
4. *Consistency of administration*. The extent to which selection procedures are used consistently across applicants
5. *Feedback*. The extent to which applicants receive timely and informative feedback
6. *Selection information*. The extent to which applicants are informed how the test and selection procedures will be used and why they are used
7. *Honesty*. The extent to which recruiters and test administrators are truthful and honest in their communication with applicants
8. *Interpersonal effectiveness of administrator*. The extent to which applicants are treated with respect and warmth from the test administrator
9. *Two-way communication*. The extent to which applicants have the opportunity to offer input and to have their views on the selection process considered
10. *Propriety of questions*. The extent to which questions on tests are appropriate and not offensive

Distributive Justice Rules

1. *Equity*. The extent to which applicants perceive that the outcome of the selection process (whether they are hired or not) is based on competence or merit
2. *Equality*. The extent to which applicants, regardless of knowledge, skills, and abilities, have an equal chance of being hired for the job
3. *Needs*. The extent to which job offers are distributed on the basis of individual needs (e.g., preferential treatment for a subgroup)

CONSEQUENCES OF APPLICANT REACTIONS

Applicant reactions toward selection procedures have been found to affect a number of important outcomes, both directly and indirectly. It has been shown that when applicants react positively toward a test, they are more likely to accept a job offer from the company, recommend the company to others, reapply for a job with the company, and perform well once they are employed by the company. It has also been suggested

that negative applicant reactions may result in a greater number of employment lawsuits and a decreased probability an applicant will buy the company's products in the future.

One of the most important consequences of applicant reactions is the effect reactions have on applicant test performance. However, this research has almost exclusively examined the effects of applicant reactions on cognitive ability test performance and has neglected the effects of reactions on other test measures. This research has shown that when applicants react favorably to a cognitive ability test, they are more likely to perform well on the test, although the effects are modest.

REACTIONS TOWARD DIFFERENT SELECTION MEASURES

Initial applicant reactions research focused on comparing reactions to different types of measures. For example, research suggests that reactions toward assessment centers and work simulations tend to be more favorable than paper-and-pencil tests (e.g., cognitive ability measures). The reasoning is that assessment centers and work simulations appear to be more job-related and therefore result in more favorable reactions on the part of the test taker. Further, research suggests that personality measures tend to be perceived less favorably than other types of selection measures.

Although tests seem to differ in the reactions they evoke, research suggests that reactions toward tests can be altered in several ways. For example, research has shown that making a test more job-related will result in more favorable applicant reactions. That is, by ensuring that the content of the test (regardless of test type) reflects the content of the job, one can increase the likelihood that applicants will respond favorably to the test. Further, research suggests that providing an explanation for why the test is used can make reactions toward the test more favorable, as can making selection decisions in a timely manner.

TEST-TAKING MOTIVATION

Test-taking motivation is an important component in all applicant reactions models. One of the most important and researched outcomes of applicant reactions is test performance, and research has clearly shown that test-taking motivation partially mediates

the relationship between applicant reactions and test performance. It has been found that when applicants have favorable reactions toward a test or testing process, they perform better on the tests.

More recently, researchers have sought to determine precisely how motivation mediates the relationship between applicant reactions and test performance by considering the multidimensional nature of motivation. Based on an established theory of motivation, VIE (valence-instrumentality-expectancy) theory, a multidimensional measure of test-taking motivation has been developed. The three components of VIE theory are defined as follows. *Valence* is the desirability or attractiveness of an outcome. *Instrumentality* is the belief that a behavior will lead to a specified outcome. *Expectancy* is the subjective probability that effort will lead to a specified outcome. In a testing context, *valence* refers to the value one places on getting the job for which one is taking the test, *instrumentality* is the belief that good test performance will lead to one getting the job, and *expectancy* is the expectation that one will do well on the test if one puts effort into doing well. Early results suggest that these three dimensions of test-taking motivation are distinct, as they demonstrate different relationships with test performance and applicant reactions.

PRE- AND POSTTEST REACTIONS

Some research has examined both pre- and posttest reactions and how time of measurement influences relationships. Pretest reaction measures are administered before the applicant takes the test or takes part in the selection process in question. Posttest reaction measures are administered after the applicant has taken the test or been through the selection process. Research generally finds that responses to pre- and posttest reaction measures are similar but not identical. Therefore, researchers have tried to understand precisely why pre- and posttest measures are sometimes different.

In particular, the self-serving bias may explain how applicants respond to posttest reactions and motivation. Specifically, if applicants have already taken a test, their perceptions of how they performed may influence their reported test reactions and test-taking motivation. Those who believe they did poorly on the test may be inclined to blame the test and report that they have negative test reactions or indicate that they did not even try to do well on the test (i.e., they report

low test-taking motivation). Attributing one's negative performance to lack of effort or to a problematic test may help protect one's self-esteem. Given these findings, it is important for researchers to be aware that pre- and posttest reaction measures may result in different outcomes.

RACE DIFFERENCES IN APPLICANT REACTIONS

Racial differences in applicant reactions exist, with Blacks and Hispanics being more likely to have negative reactions than White individuals. It is believed that these race differences in applicant reactions may contribute to race differences in test performance. In particular, it is well documented that White individuals, on average, score substantially higher on cognitive ability tests than Black and Hispanic individuals. It is believed that differences in applicant reactions may contribute to the differences between how Whites and minorities perform on cognitive ability tests. Therefore, considerable research has focused on how applicant reactions may affect the race–test performance relationship. Research has shown that race predicts test reactions, test reactions predict test-taking motivation, and test-taking motivation influences test performance. Thus, race differences on tests may be larger when minority reactions are negative because minorities will have lower test-taking motivation and hence lower test performance. Although research shows that reactions indirectly account for significant variance in race–test performance relationships, applicant reactions do not account for the majority of race differences in test performance.

PRACTICAL IMPLICATIONS OF APPLICANT REACTIONS RESEARCH

As noted earlier, applicant reactions have a number of important consequences. Therefore, test administrators and human resource professionals would be wise to make applicant reactions to selection procedures as favorable as possible. This is especially true when an organization is trying to meet diversity goals. Research suggests that minorities tend to have less favorable reactions toward selection procedures than majority group members. Therefore, minorities will be more likely to self-select out of the selection process or even be less inclined to take a job if one were offered. Research also suggests that the more qualified job

applicants are likely to be most influenced by how they perceive the selection process. Thus, ensuring that selection procedures are viewed favorably by applicants may have the added benefits of increasing minority representation in the selection process and retaining the most qualified job applicants.

To increase the chances that tests are perceived favorably by applicants, organizations can ensure the tests they use are job-related, provide explanations for why the test is being used (e.g., the test administrator can provide information about the validity of the measure), explain how the selection process will proceed (e.g., clearly explain the stages of the selection process), provide feedback to applicants in a timely manner, and treat applicants consistently and with respect throughout the selection process. Doing so may result in more favorable reactions.

ARMY ALPHA/ARMY BETA

The United States entered World War I late in the conflict and faced the problem of turning large numbers of often poorly educated draftees into an effective army in a short period of time. The American Psychological Association volunteered its services to the war effort, and a committee, headed by Robert Yerkes and including psychologists such as Arthur Otis and Lewis Terman, was assigned the task of developing a practical method of measuring the intellectual level of individuals in large groups. Their efforts led to the development of two tests, Army Alpha and Army Beta. Army Alpha was a written test that could be administered to large groups of recruits and that provided a rough measure of general intelligence. Army Beta, a nonverbal test designed for illiterates and for recruits who spoke little or no English, could also be administered to groups and used simple pictorial and nonverbal instructions.

Army Alpha was made up of 212 true–false and multiple-choice items, divided into eight subscales: (a) oral directions, which assessed the ability to follow simple directions; (b) arithmetical problems; (c) practical judgment problems; (d) synonym–antonym items; (e) disarranged sentences, which required subjects to rearrange fragments into complete sequences; (f) number series completion, which required examinees to infer and complete patterns in series of numbers; (g) analogies; and (h) information, a general knowledge subtest. The most basic purposes of Army Alpha were to determine whether recruits could read English and to help in assigning new soldiers to tasks and training that were consistent with their abilities. Several of the scales and test formats developed by Yerkes and his colleagues for Army Alpha are forerunners of tests still in use today.

Many draftees were unable to respond to written tests, because of their limited literacy or their limited command of English; Army Beta was developed to assess the abilities of these examinees. The instructions

for the Beta test were given in pantomime, using pictures and other symbolic material to help orient examinees to the tasks that made up this test. Army Beta included seven subscales: (a) maze, which required looking at a graphic maze and identifying the path to be taken; (b) cube analysis, which required counting cubes in the picture; (c) X-O series, which required reading symbol series to identify patterns; (d) digit symbol, which required matching digits and symbols; (e) number checking, which required scanning and matching graphic symbols in numeric forms; (f) picture completion, which required examinees to identify features required to complete a partial picture; and (g) geometrical construction, which required examinees to manipulate forms to complete a geometrical pattern.

ADMINISTRATION AND USE OF ARMY ALPHA AND ARMY BETA

The Army Alpha and Army Beta were administered to more than 1.5 million examinees. Scoring guidelines were developed with the aim of making Army Alpha and Army Beta roughly comparable. Scores on both tests were sorted into eight order categories (A, B, C+, C, C–, D, D–, E). Those with the lowest letter grade were generally considered unfit for service. Examinees receiving grades of D or D– were recommended for assignment to simple duties, working under close supervision. Examinees with scores in the middle of the test score distribution were recommended for normal soldier duties, whereas men receiving higher scores were recommended for training as noncommissioned officers and for officer training.

Army Alpha and Army Beta were perceived as useful at the time they were introduced. These tests provided at least a rough classification of men, which was of considerable utility in making the large number of selection decisions necessary at that time. The apparent success of the army's group tests did not go unnoticed in business circles and educational settings. Soon after the war, the demand arose for similar tests in civilian settings; by the mid- to late 1920s, intelligence testing was widespread, particularly in schools.

CONTROVERSY OVER ARMY ALPHA AND ARMY BETA

The use of psychological tests to make high-stakes decisions about large numbers of individuals was controversial at the time these tests were developed, and

Army Alpha and Army Beta continue to be sources of controversy. First, many of the psychologists who developed these tests were extreme proponents of hereditarian points of view and often were enthusiastic supporters of the eugenics movement. Yerkes and his colleagues used Army Alpha and Army Beta data to argue against immigration and racial mixing, claiming that the addition of intellectually inferior races and groups to the American melting pot was responsible for what they regarded as low levels of intelligence in the American population. Psychologists involved in the development of Army Alpha and Army Beta played a prominent role in supporting legislation after World War I that greatly curtailed immigration.

Second, serious doubts were raised about the validity and the utility of both tests, particularly Army Beta. Despite efforts to train test administrators, Army Beta could be a particularly intimidating and confusing experience, and it is unclear whether this test provided useful information. More generally, evidence that Army Alpha and Army Beta actually contributed to the success of the army in assimilating and training the vast group who were tested is thin. In part, the problem lies with the fact that the United States entered the war so late that the success or failure of this test was simply hard to gauge. Army Alpha and Army Beta were a tremendous administrative success—they allowed the army to quickly process huge numbers of recruits. However, this set of recruits barely had time to receive training and were mustered out of the army shortly after the conclusion of the war. The hypothesis that the use of these tests led to better decisions than would have been made using more traditional (largely subjective) methods of classification simply could not be tested during World War I. The documented validity and utility of successors to Army Alpha and Army Beta suggest that these tests were likely to make a real contribution, but definitive data about the impact of these tests does not exist.

Finally, controversy over Army Alpha and Army Beta reflected broader controversy over the value (if any) of psychological testing in general and intelligence testing in particular. Early proponents of psychological testing sometimes made extravagant claims about the value and the importance of these tests, and there was a substantial backlash against the more sweeping claims about the importance, validity, and implications of tests like Army Alpha and Army Beta.

ASSESSMENT CENTER

The *assessment center* is a skills-evaluation process that has been used historically in selection and placement decision making, in employee skill development, and more broadly in career development and organizational succession planning. The process was initially developed in the 1930s by the German military for the primary purpose of officer selection. The methodology was adopted, based on familiarity with the German model, shortly thereafter by the British military for similar purposes, and subsequently by the Australian and Canadian militaries.

The assessment center process was first used in the United States by the Office of Strategic Services (OSS) during the middle to late years of America's involvement in World War II (1943 to 1945), to help in the selection of operatives for spy missions. The personality theorist Henry Murray had earlier developed and applied a multiple assessment methodology in a research project aimed at better understanding personality. Subsequently, Murray participated fully in the creation and implementation of the OSS assessment center, which also borrowed heavily from the earlier German and British efforts. For a variety of reasons, including Murray's strong influence, the three-day OSS assessment process was centered on measuring relatively holistic personality variables, rather than job-specific competencies.

The first publicized business application of the assessment center methodology took place at AT&T in the mid-1950s, in what was called the Management Progress Study, conceived and led by Douglas Bray.

The classical AT&T assessment center became the prototype of the many business applications that were to follow. The AT&T process was built directly on the OSS model, but with heavier emphasis on exercises comprising situational, job-sample tests to assess job-related competencies than on the assessment of holistic personality variables.

The AT&T process was aimed at aiding in the selection and development of managers for the company. Several hundred candidates were assessed in groups of 12 in a three-and-a-half-day process, spread over a four-year period. Initially, a set of characteristics of successful managers, or what we would now call *management competencies*, was identified based on literature review and the judgment of AT&T internal subject matter experts. Note that no explicit job analysis was done to identify these characteristics of successful managers. Then a series of activities was created that would allow the assessors to rate participants in each identified skill area. Activities included a series of in-basket activities (still a standard feature of management assessment centers), leaderless group discussions (also a centerpiece of the methodology), and a variety of individual and group problem-solving situations. The issues dealt with were selected to be realistic ones for the job of manager in the organization. In addition to such high-fidelity job-related activities, several projective and structured personality inventories were given, participants were interviewed extensively, and each was required to write an autobiographical essay. The assessors were largely a mix of consultants and psychologists, with some involvement of AT&T incumbent managers, as well.

Since the foundational AT&T study, the assessment center methodology has been refined, researched, and applied internationally and domestically, in a wide variety of work settings, prominently including government work (especially police and fire departments), service industries, and industrial settings. These subsequent applications of the assessment center methodology still draw on many of the core features of the seminal AT&T program.

So widespread has the methodology become that specific and detailed structural, ethical, and professional guidelines have been established by an organization called the International Task Force on Assessment Center Guidelines. In the most current version of those guidelines (the first were codified in 1975), 10 essential elements of the assessment center methodology, which must be present for a process to

be considered an assessment center, are identified, as follows:

1. *Job analysis.* Required to establish the critical, relevant, observable performance elements and competency categories to be assessed. Competency-modeling procedures may be substituted for classical job analysis. The point is to establish through rigorous methods the observable behaviors and competencies to be assessed.
2. *Behavioral classification.* Behaviors demonstrated by participants must be classified and categorized into dimensions, skills, competencies, abilities, and so forth.
3. *Assessment techniques.* Must be designed to reveal performance relative to the key dimensions and competencies that are critical in the performance of the job.
4. *Multiple assessments.* A mix of techniques must be selected to allow behaviors revealing of the critical competencies to be observed and assessed.
5. *Simulations.* The techniques employed must include job-related simulations, although the assessment center overall need not be limited to job-related simulations. Although relatively low-fidelity simulations may be adequate for some purposes, especially early-career selection programs for nonmanagement jobs, high-fidelity simulations are preferred, especially for developmental (not only or mainly selection) programs for experienced, high-level incumbents. Acceptable simulations require that the assessee actually demonstrate behaviors, not merely select from a list of multiple-choice options or state intended actions.
6. *Assessors.* Multiple assessors observe and assess each participant, with a typical ratio of 1:2. Assessors should not be immediate supervisors of a participant. Diversity (functional, ethnic, organizational level, gender) in the pool of assessors is considered highly desirable.
7. *Assessor training.* Assessors must demonstrate competence in their role, based on targeted assessor training prior to using those skills. Typically, assessors should receive two days of training for each day of the assessment process itself.
8. *Recording behavior.* Assessors may not rely solely on memory but must document through notes, behavioral/competency checklists, video recording, or some similar method that allows later review.

9. *Reports.* It is expected that assessors draft preliminary reports, based on their records of the behavior of assesseees.
10. *Data integration.* Assessors are required to pool their observations through some accepted methodology, such that final reports represent the integration of all relevant data.

The assessment center process sometimes runs for only a day, or even less, but more commonly is a multiday affair, with the period of two to five consecutive days being common. Assesseees are always put through the process in groups (the typical size being 6 to 12 participants in a center, assessed by three to six assessors, although there are exceptions to these dimensions). Assessors, usually higher-level managers in the company, sometimes aided by psychologists or other consultants, typically do not know the participants they are assessing. However, there is some recent evidence to suggest that center ratings may have higher criterion-related validity when in fact the assessors are familiar with the participants they are assessing.

Some applications of the methodology aim mainly or exclusively at selection. When that is the case, it is common for participants to receive feedback that includes only or mainly the final hiring recommendation and to be given the rationale for that recommendation only on request. When the primary goal is development, however, and whenever the assesseees are current members of the organization, participants are typically given much more detailed feedback, usually including the final feedback report. Indeed, where assessment centers are part of a broader career-planning and/or succession-planning process, it is common for the feedback shared with the participant to be highly detailed and for extensive developmental planning and coaching to be included as a key element in the overall assessment process.

Although the focus of the assessment center is mainly on profiling the competencies of the individual, there are numerous collateral benefits. A well-designed center gives candidates a kind of realistic job preview. Also, when an organization has assessed a number of internal candidates, the organization can get a valuable perspective on where general skill strengths and deficits are by averaging across the individual profiles. Thus, for example, if most internal candidates score poorly on the competency of delegation, and the company in question has legitimately determined that such skills are indeed important in the

role being assessed, such data can be used to support training and development programs and other relevant skill-building processes in the organization. Such a finding could also affect the company's recruiting and hiring strategies. Similarly, longer-range succession planning is supported by having assessment data on a pool of incumbent employees who have the core skills necessary for higher-level jobs. In general terms, assessment centers can provide a level of information that is valuable to the organization, beyond the skills and developmental needs of individual candidates.

Since the introduction of the assessment center concept into business in the 1950s, the methodology has been employed by thousands of organizations. Recent estimates indicate that assessment centers in one form or another are used regularly by as many as 2,000 companies in the United States, and perhaps as many as 70% of large organizations in the United Kingdom. They are widespread in industry in other parts of Europe, as well. Additionally, they are particularly likely to be used by public-sector organizations such as local police and fire departments.

There is a huge base of research on the assessment center methodology. Despite some flexibility and variability in how the methodology is applied (e.g., number and kinds of activities, duration of the center, level of training of assessors, and even the extent to which the guidelines are adhered to), the data generally support the conclusion that assessment center scores show very good criterion-related validity in predicting job performance in the role being assessed. On average, meta-analyses across many studies show criterion-related validity estimates for a broad range of indicators of performance in the $+0.35$ to $+0.45$ range, and often higher for certain submeasures or for composite measures. Also, assessment center results have shown reasonable validity generalization across different jobs within broad job families. It is also often noted that compared with other selection and development approaches, the assessment center methodology has very high face or content validity, as judged by candidates, assessors, and other subject matter experts alike. Thus, the level of participant acceptance of the process is typically high. Further, it is widely claimed that compared with other selection processes, assessment centers are fair. In general, they are found not to discriminate against women, minorities, or other groups protected by the Equal Employment Opportunity Commission. In short, they are so popular because they work and are legally defensible. (Note, though,

that there is some recent evidence that older candidates may be rated generally lower than younger candidates, suggesting the possibility of age bias.)

Primary criticisms of the assessment center methodology center on complexity and cost. Developing and running an effective high-fidelity assessment center is time-consuming and expensive, to the extent that unless it is going to be run many times, it may be cost prohibitive for an organization to develop one. Even if it is to be run multiple times, each session is time-consuming and expensive in itself, requiring training time for assessors and a significant time commitment for assessors, participants, role players, administrators, and so on during the session. Thus, the methodology is used more by large organizations that have large numbers of managers and potential managers, and where the costs of a poor selection or career development decision are great. In such cases, again, the assessment center methodology is widely supported as a valuable selection and development tool.

The lack of construct validity has also been identified as a criticism of the assessment center methodology. It has been found in terms of convergent and especially discriminant validity; there is sometimes little consistency between a participant's scores on a given competency from one exercise to another, and within a given exercise, scores on different dimensions are often highly correlated. Recent research aims at determining why assessment centers are so effective in terms of their ability to predict job success, despite the lack of demonstrated construct validity.

One current trend of note is the growing use of technology as an aid to the assessment process. Thus, there is increasing use of video recording of participants' performance during the session, allowing later review by assessors and enhancing the feedback opportunities for participants, including self-feedback. Also, there is increasing use of the computer as an aid in integrating scores across different assessors. Additionally, as communications technology has become more widespread in the workplace, there is less reliance on paper-and-pencil activities and increased use of tools such as voice mail and e-mail as the more ecologically valid in-basket of today's workplace.

There is an increase in the integration of various forms of 360-degree feedback processes (usually abbreviated compared with conventional stand-alone 360s) into the assessment center feedback package, such that those familiar with the work of the assessee contribute to a richer overall feedback experience for participants.

Another growing trend is toward more integrated total or continuous simulations, rather than a bits-and-pieces, stop-start approach that takes each exercise as a discrete event. Participants in continuous simulations are assigned a role, with relevant background information about that role, including a set of role players with whom they may interact in the course of the center. Participants and role players then stay in role for the duration of the session.

To combat the high cost and time investment of the classical assessment center, there is also a developing trend toward what is being called *ongoing assessment*, for career developmental purposes. In this application, internal candidates may meet briefly with assessors at mutually convenient times to do more or less standard assessment center exercises. Rather than conducting the assessment intensively over a period of a few days, it may be spread over several weeks in and around other work responsibilities, thus being accomplished in a less labor-intensive and costly format.

The methodology is now being increasingly extended beyond the traditional target group of managers and potential managers to include candidates for positions such as members of self-directed work teams. Indeed, the need to qualify people for such expanded roles (including leadership roles in the flexible, high-performance workplace) has become a primary impetus for the application of the methodology.

From its earliest applications in the organizational setting, the assessment center has grown to be a major tool for selection, promotion, and development of critical organizational talent around the world. Researchers continue vigorous programs to determine why assessment centers work to the extent they do and how they can be made more effective.

ASSESSMENT CENTER METHODS

The assessment center is a methodology used to select, promote, and develop people, usually managers, in an organization. From the earliest efforts in the 1930s and 1940s in the military, aimed at selecting officers and key operatives for highly sensitive missions, to the first systematic application in the organizational setting in the 1950s, the assessment center has become a familiar tool for skills evaluation.

A defining feature of the assessment center methodology is that it comprises a battery of tests. Further, the tests must represent a multiplicity of types. No single instrument or single type of instrument is sufficient to qualify a skills assessment process as an assessment center, by that name, according to the International Task Force on Assessment Center Guidelines.

The earliest iterations of the assessment center methodology focused to a significant extent on individual-differences assessment. The American military application, for the selection of spy operatives in World War II, was influenced strongly by the work of Harvard psychologist and noted personality theorist Henry Murray and included a good deal of personality profiling. It is still common today for personality assessment to be incorporated into an overall battery of assessment center instruments. With the development of the five-factor model of personality, the NEO tests have become an increasingly familiar part of the overall assessment center process. There are recent data suggesting that scores on the conscientiousness and extraversion scales, in particular, may generally

correlate with overall assessment center scores. At any rate, especially where the focus is more on development and less on near-term selection, personality feedback is commonly part of the assessment process.

Tests of general cognitive ability are also sometimes included as a collateral part of the assessment center process. Much like personality tests, cognitive abilities tests represent a source of additional feedback to the assessee, as well as potential predictors of future work success. Cognitive ability scores do correlate significantly with overall assessment center scores, which in turn are broadly predictive of job success.

Interviews are another familiar support tool of the assessment center methodology. The interviews may be very general, unstructured ones, aimed at identifying the assessee's background, interests, career goals, and so forth. Or they may be more structured, even situational, in which case they may form integral parts of the assessment process. A typical situational interview would describe a scenario of the sort an incumbent might experience at work—say, problems with an upset customer, a conflict between sales and operations, or an employee not following safety procedures. After specifying the situation in detail, interviewers would ask the assessee how he or she would handle the situation. The assessee's answers would then be rated in terms of the underlying competencies being assessed (e.g., relationship management, communication, problem solving).

Beyond personality or intelligence assessment and interviews, the heart of the assessment center methodology is a series of individual and group activities in which candidates, working individually or in various groupings, handle work-related problems and issues. Many of these individual and group exercises were pioneered in the earliest applications of the methodology and continue to be centerpieces of the assessment center process. Included in this mix of classical methods are the venerable in-basket, leaderless group discussions, and role plays.

The in-basket is sometimes considered *the* defining tool of the assessment center methodology. The basic idea of the in-basket is that participants are assigned a role, namely the role for which they are being assessed, and are given the kinds of memos, reports, notes, and other communications that an incumbent in the role being assessed might receive in her or his in-basket on a given day. The participants must then act on the in-basket information in the way they would in the

real world, prioritizing issues, writing reply memos, gathering information, calling meetings, and so on. It is common for the in-basket exercise to be timed. When possible, participants might subsequently be interviewed after the exercise, to better understand the rationale for their responses to in-basket items.

The in-basket provides opportunities to observe how the participant prioritizes and plans, solves problems and makes decisions, and communicates and coordinates with key resources, for example, all of which are common competencies of the managerial role. In-basket activities can be considered a kind of multidimensional work sample test, to the extent that the role being assessed requires just such handling of incoming communications.

One benefit of the in-basket method is that it typically includes some documented output by the participant. The written recommendation, or market analysis, or meeting agenda, or reply memo is a piece of data that assessors can review and reflect on offline at their leisure, assisting them in the skills evaluation process.

Today, managers spend quite a bit less time than in the past handling memos in paper form and a much greater amount of time in e-mail, voice mail, and cell phone communication. It is increasingly common for the methodology of high-fidelity assessment centers to reflect current technology. Thus, participants' workspace in a modern assessment center may include a desktop computer, through which they can receive and send e-mails, and a phone/voice mail system, through which they can communicate with others. The availability of such technology greatly increases the fidelity of the work setting in the assessment center but also greatly increases the workload on the assessors who have to keep track of such rapid communication via multimedia for several participants.

The leaderless group discussion is also a familiar classical feature of the assessment center methodology. Typically, participants are given an issue to discuss and make recommendations about. As the title suggests, no member of the group is formally designated as leader. They may be told, for example, that they are all regional sales managers for XYZ Corp., which is facing a declining market, new competition, and quality problems in production. They are then asked to meet and fully discuss the issues and make a recommendation to the vice president/general manager on how to address the problems. They will have been given sufficient information (e.g., through

in-basket communications) for them to think strategically about the problems. In some cases, individual participants are given different information, or different perspectives on the issue at hand, such that disagreement and conflict are more likely in the discussion.

In the course of the leaderless group discussion, participants gravitate to roles in which they are comfortable. Usually, someone will structure the meeting approach, someone will keep notes, some bring organized proposals, some brainstorm well, some show skill at developing others' ideas, and some participate little. The format provides an excellent opportunity for assessors to see a whole range of competencies related to communication, influence, collaboration, resolving disagreements, problem solving, relationship management, and the like. To the extent that the contemporary environment of work puts a premium on joint, collaborative work and the ability to cooperate and compromise as well as provide direction, this tool gives assessors a snapshot of candidates' interactive skills and general approach to teamwork. The leaderless group discussion has been called the *projective test of leadership*. If the scenario is realistic and engaging, participants can get caught up in the issue and reveal much about their real approach to collaborative work. One caution is that strong individual personalities can shift the dynamics of a leaderless group such that it is hard to get a valid view of each individual's approach. For example, one extremely competitive participant can cause others to become more aggressive, or for that matter more compliant, than they normally would be. Assessors must be alert to such artifacts.

In the role-play method, participants are given a role and a scenario to act on with a role player/assessor, whose role is also specified. At the appointed time, the assessee and the role player interact as assessors observe and make notes. For example, a participant may be in the role of a supervisor in a team-based production environment whose crew has been complaining about how the previous shift leaves a mess that they have to clean up before they can start running production. They have asked her to talk with the peer supervisor of the off-going shift (played by the role player). The role player is provided with specific guidelines as to how to act and the kinds of themes to weave into the role play (e.g., be a bit defensive—express thoughts such as “I don't tell *you* how to run *your* shift!”). He is further directed to act realistically

to that role and to base further responses on the approach the assessee takes to the problem. Finally, he is asked to keep in mind that the point of the role play, as with all of the exercises of the center, is to provide a realistic forum in which to see the participant's skill level on key competencies, so he should give the participant ample opportunity to show active listening skills, project empathy, be results oriented, and so on.

Beyond the classic "big three," additional exercises that are often found in assessment centers include structured meetings, presentations, and written analyses. In a structured meeting, the participant's role is specified. Thus the participant might be a sales manager leading a meeting with his three sales reps around a given market issue. An example of a presentation might be a 10-minute overview of plant status by a plant manager, given to his boss (role player), or a sales presentation given by a sales manager to a national client (role player). Written analyses might include completing a budget or doing a cost justification for the purchase of a major piece of equipment. Again, as always, such exercises are anchored in the competencies that are being assessed.

Finally, it is normal for some self-assessment (and at times 360-degree feedback) to be included in the overall assessment center process. Early iterations of the methodology had participants write autobiographical statements. More recent applications may directly call for self-assessment, such as "On a five-point scale, rate your ability in the area of delegation . . . what are your specific strengths in this area . . . what are your specific developmental needs in this area?" Or activities may be built into other exercises that precipitate such self-assessment indirectly. Thus, an in-basket memo from the boss might ask the participant to list what he or she sees as the critical competencies of the job in question and to self-assess and identify personal training and development needs in these skill areas.

A major methodological question centers on the level of fidelity of the simulations in the assessment center. Especially if the goal of the process is to select nonmanagerial employees from a pool of outside applicants, it is common for the center to be brief (1 day or less) and relatively low-fidelity. Thus activities might be more generic (e.g., a leaderless group discussion about how to motivate employees) than detailed and specific to the role (a leaderless group discussion about changes to a specific incentive bonus plan, based on information given in the in-basket). With internal candidates, and especially for managerial

positions, it is common for the process to be longer (on the order of 2 to 5 days), more detailed, and higher-fidelity. Also, under the latter circumstances it is common for the various exercises of the assessment process to be integrated rather than discrete. That is, candidates will be given highly detailed information about their role at the outset of the process. Thus, if they are in the role of a plant manager in a manufacturing environment, they will be given specifications such as a personal work history (how long they have been in that role, where they worked before), the parameters of their plant, organizational charts, detailed information on their division and company, recent history of their plant, background on their employees, and key challenges facing their plant. Then from the time the center begins until it is concluded, they stay in that role. All the issues that come up are consistent with the information they have been given. They role play with key individuals who have been identified in the initial information they have received (e.g., their boss, their sales counterpart, key direct-report employees, the union president). Such an integrated total simulation approach, if well designed, is typically seen by participants as having especially high face validity.

Modern technology is not only used to increase the fidelity of the work simulation for participants. It is also used as a powerful aid to the assessor in the roles of observer, role player, behavior analyzer, and report writer. For example, it is increasingly common for assessors to videotape group discussions, role-play interactions, presentations, and so on. Then the tapes can be reviewed later for more detailed and thorough analysis. Additionally, the videos can be incorporated directly into the feedback process, potentially enriching the experience for the participant. Technology can also be used for the delivery of some elements of the assessment process, including personality profiles or cognitive-abilities assessments, online.

In general, given the complexity and cost of assessment centers, there is constant pressure to simplify and shorten assessment centers without sacrificing fidelity and predictiveness. Thus, there is some movement toward the use of online situational interviews in which participants choose a multiple-choice response as their output. Such an item can be taken by an individual quickly and automatically scored and integrated with other scores. In a similar vein, there is a move toward a less formalized overall approach to assessment centers, in which the assessment is done

with internal candidates, typically individually, in brief interactions over a longer period of time, still using assessment center tools such as in-basket activities and role plays. One distinct advantage of such ongoing assessment is that it can be done when the company has fewer than the usual 6 to 12 candidates but needs to assess competencies in a couple of key individuals now. Such truncated methods can be built to have good criterion-related validity, even though they are not fully consistent with the guidelines of the International Task Force on Assessment Centers. In the contemporary organizational climate of change, it is expected that such variations on the core methods of the assessment center will be increasingly common.

ATTITUDES AND BELIEFS

Attitudes are the positive or negative evaluations made about people, issues, or objects. For example, in an organizational setting, employees might hold attitudes toward their employer or coworkers, toward workplace issues or regulations, and toward the job itself.

Attitudes form a central foundation of the way that individuals think about and come to understand the world around them; consequently, they influence and are influenced by people's beliefs and cognitions. Much research has focused on the structure and measurement of attitudes, as well as their relation to affect, beliefs, and behavior. A central question that has been raised with regard to attitudes is whether they are accurate predictors of behavior. Understanding processes of attitude formation and change has also been a dominant avenue of research.

ATTITUDE STRUCTURE

Attitudes are based on cognitive, affective, and behavioral information. Beliefs provide the cognitive basis of an attitude. A *belief* is the cognitive information that one has about an attitude object. For example, a workplace attitude might be based on beliefs, or cognitions, about one's job. The *affective basis* of an attitude refers to the emotional response that one has toward the attitude object—for example, the affect that one feels toward one's job. The *behavioral basis* of an attitude refers to actions that are taken with regard to the attitude object, such as job-related behaviors that reflect one's attitude toward work. An attitude might be based on any combination of these three components. For certain attitudes, components can be evaluatively inconsistent with one another. For example, a person with an emotionally grueling job might experience negative affect toward his or her work but at the same time hold positive cognitions by believing that the job is important and useful. This leads to attitudinal ambivalence, which is described as a state of holding *both* positive and negative evaluations of the same attitude object.

The issue of attitudinal ambivalence has received recent attention, reflected in the debate over whether attitude structure is bipolar or bivariate. Evaluative processes have been traditionally conceptualized as bipolar. According to a bipolar model of attitudes, people's attitudes can range from very negative (and not at all positive) to very positive (and not at all negative). This conceptualization implies that negativity and positivity are reciprocal, opposing forces; consequently, the more positive one's attitude is, the less negative it will be, and vice versa. One limitation of this conceptualization is that it precludes the possibility of attitude ambivalence. To address this issue, an alternative conceptualization of attitude structure has

emerged in which attitudes are viewed as bivariate rather than bipolar. The bivariate perspective suggests that positivity and negativity are separable attitudinal substrates, rather than opposite ends of the same continuum; further, each can be separately activated and exert an independent influence on behavior.

ATTITUDE FORMATION

Attitudes form through a variety of processes. Many attitudes are developed through direct experience with an attitude object or learned through processes of operant and classical conditioning. A growing body of evidence suggests that attitudes may also have a genetic basis.

Direct experience. Attitudes may form through direct experience with a person, issue, or object. Direct interaction with the attitude object contributes to the formation of a positive or negative evaluation. Attitudes formed through direct experience are strong predictors of future behavior.

Classical conditioning. When a positive or negative stimulus is paired repeatedly with an initially neutral attitude object, attitude formation through classical conditioning may occur. When this occurs, the evaluation paired with the neutral stimulus eventually becomes associated with the attitude object itself. Attitude formation through this process often occurs at an unconscious level.

Operant conditioning. Attitudes are formed through operant conditioning when an attitude object becomes associated with a positive or negative consequence. Specifically, when behavior toward an attitude object is reinforced, a positive attitude toward the attitude object will form. When behavior toward an attitude object is punished or associated with negative consequences, an unfavorable attitude will form.

Genetic determinants of attitudes. Identical twins (even when raised in separate environments) show a higher correlation in their attitudes than fraternal twins, providing evidence for a genetic basis of attitudes. This is likely because of the influence of genetics on temperament and personality, which in turn influence attitudes. Attitudes that have a genetic basis appear to be more difficult to alter and exert a stronger influence on behavior.

IMPLICIT AND EXPLICIT ATTITUDES

A distinction has been made between *implicit* and *explicit* attitudes. An explicit attitude is one that a

person is consciously aware of and can report, for example, on a self-report measure. A large volume of research has focused on understanding and assessing explicit attitudes. However, recent attention has turned to the existence of implicit attitudes, attitudes that are involuntary, uncontrollable, and, in some cases, not accessible at a conscious level. Although implicit attitudes are not consciously accessed, they are found to still exert influence on behavior. Take, for example, a person who holds sexist attitudes in the workplace but is not consciously aware of holding these attitudes. These are implicit attitudes, which could exert influence on this person's workplace behavior with regard to female employees. The relationship between implicit and explicit attitudes, along with their influence on behavior, is a topic of ongoing investigation among attitude researchers. With regard to attitude measurement, implicit and explicit attitudes may require different methods of assessment. Because people are not able to directly access and report implicit attitudes, traditional means of attitude measurement may be less effective, indicating a need for more indirect methods of assessment.

ATTITUDE MEASUREMENT

Attitudes are frequently assessed through self-report measures. Three common scale methodologies used to assess attitudes are the Thurstone scale, Likert scale, and semantic differential. A Thurstone scale is developed by having individuals rank order opinion statements about a particular attitude object according to their favorableness. A subset of items representing a wide range of opinions is then selected and used to assess attitudes. A Likert scale consists of a series of items for which people indicate the strength of their agreement with each statement (e.g., "I enjoy my job") on a rating scale that encompasses low to high levels of agreement. The semantic differential assesses attitudes by providing opposing adjective pairs (e.g., good–bad; foolish–wise) on which the individual rates a specific attitude object.

Although there are advantages to measuring attitudes through direct self-report measures, such as availability, speed, and ease of use, there are also limitations associated with their use. For example, many existing self-report measures make the implicit assumption that attitudes are bipolar (rather than bivariate) and, therefore, may not detect levels of attitudinal ambivalence. Further, when individuals are

asked to report attitudes on controversial topics, they may be less likely to report their true evaluations and instead report responses that they perceive to be socially desirable. Similarly, if attitudes are not consciously accessible, as in the case of implicit attitudes, individuals may not be able to accurately report them on these measures. To overcome these concerns, researchers can use indirect methods of attitude measurement, such as unobtrusive behavioral measures, physiological measures, or techniques, such as the Implicit Association Test, that are designed for assessing implicit attitudes.

DO ATTITUDES PREDICT BEHAVIORS?

The question of whether attitudes guide and predict behavior is an issue that has been central to the study of attitudes. Several critical challenges to the commonsense assumption that attitudes determine behavior emerged in the 1930s and 1940s, as numerous studies indicated little or no relationship between attitudes and behaviors. Consequently, by the 1960s there was a call by many researchers to abandon the study of the attitude. Since then, researchers have reexamined the attitude–behavior link and articulated particular conditions under which attitudes will be likely to guide behavior. Attitudes that are accessible, specific, strong, or formed through direct experience are found to exert stronger influences on behavior. Additionally, the theory of reasoned action, developed by Icek Ajzen and Martin Fishbein, and the theory of planned behavior, developed by Ajzen, provide models of how attitudes can guide deliberative behavior through their influence on intentions.

PERSUASION

Persuasion refers to an active attempt made to change another person's attitude toward some issue, object, or person. Seminal studies conducted during the 1940s by Carl Hovland and his research group at Yale University led to the development of the message learning approach, which became a primary template for persuasion research. The message learning approach suggests that persuasion occurs through a sequence of stages including attention, comprehension, yielding, and retention of a message. It asserts that persuasion is influenced by characteristics related to the source of the message, the nature of the audience (or message recipients), and qualities of the message itself.

In the 1980s, dual-process models, such as Shelly Chaiken's heuristic-systematic model and the elaboration likelihood model, developed by Richard Petty and John Cacioppo, emerged as dominant models of persuasion. These models suggest that persuasion can result from two types of message processing: thoughtful processing of the arguments contained in a message, or less effortful processing of cues or heuristics pertaining to the message. Whether one engages in more or less effortful processing depends on one's ability or motivation to elaborate on the message. Although attitude change can occur through either process, persuasion that results from more elaborative processing of a message has been found to be more persistent, resistant to counterpersuasion, and predictive of future behavior.

ATTRACTION–SELECTION–ATTRITION MODEL

The discipline of organizational behavior focuses on the study of organizations and the people who populate them. Generally and historically, the field has been largely divided into those who study the attributes of organizations and their markets (macro

organizational behavior) and those who study the attributes of people in organizations (micro organizational behavior). Typically, macro approaches have focused on explaining organizational performance and draw their intellectual heritage from sociology and economics, whereas micro approaches have focused on explaining and predicting individual behavior and performance and draw their heritage from psychology. Although the recent history of organizational behavior has seen attempts to integrate these two paradigms, the micro and macro distinction has led to a scholarly division with two largely non-overlapping, independent literatures. As a consequence, there is little cross-fertilization of ideas across micro and macro perspectives and little attempt to understand the processes that translate the characteristics and behavior of people to the performance of their organizations. In his 1985 presidential address to the Society of Industrial and Organizational Psychology, Benjamin Schneider noted this distinction in the literature and offered an attempt to bridge the micro and macro distinctions. In its most basic form, his model, the attraction–selection–attrition (or ASA) model, postulates that it is the characteristics of people in an organization that partially (if not largely) determine the organizational attributes typically studied by macro researchers.

OVERVIEW

The ASA model delineates a framework for understanding organizational behavior that integrates both individual (micro) and organizational (macro) perspectives by explaining macro organizational attributes with micro person characteristics. The framework proposes that the outcome of three interrelated dynamic processes, attraction–selection–attrition, determines the kinds of people in an organization, which consequently defines an organization, its structures, its processes, and, ultimately, its culture.

At the core of the ASA model are the goals of the organization originally articulated (implicitly or explicitly) by the founder. Organizational goals, and the processes, structures, and culture that emerge to facilitate attainment of these goals, are suggested to be reflections of the particular characteristics (i.e., personality) of the founder and those of his or her early colleagues. Schneider suggests that founders are faced with a variety of decisions to make regarding whom to hire, how to compensate employees, how to structure

reporting relationships, and even what industries or markets to enter. The decisions made are influenced by the underlying values, motives, and dispositions of the founder. So, for example, the ASA model would postulate that the cultural differences between Apple Computer and Microsoft had their origins in the personality differences of their founders, Steve Jobs and Bill Gates. As Apple Computer and Microsoft grew, the policies and procedures established were a reflection of their founders' early influence, and over time these policies and procedures created a culture that is somewhat unique for each company. So, the genesis of an organization's culture can be traced to the initial decisions made by founders and the unique imprint they put on their organizations. This, too, is the beginning of the ASA cycle.

The ASA cycle begins with the *attraction* process, which concerns the fact that people's preferences for particular organizations are based on some estimate of the fit or congruence of their own personal characteristics (personality, values, and motives) with the attributes of the organization they are evaluating. That is, people find organizations differentially attractive as a function of their implicit judgments of the congruence between those organizations' goals (and structures, processes, and culture as manifestations of those goals) and their own personalities. For example, an IT engineer may choose to work for Apple Computer, as opposed to Microsoft, because she or he sees the company as innovative and flexible, which conforms to the engineer's own values of creativity and independence. Ample research evidence suggests that job applicants make assessments of fit when choosing among employment alternatives.

The next step in the ASA cycle refers to the formal and informal *selection* procedures used by organizations in the recruitment and hiring of people with the attributes the organization desires. Many organizations explicitly use fit as a criterion in the hiring process. Based on ample research demonstrating that fit to an organization's culture has implications for employee job satisfaction, turnover, and absenteeism, this criterion seems justified. The greater the degree of misfit, the more likely an employee will be to experience dissatisfaction with the job, be absent, and quit. Research also suggests that fit assessments affect hiring procedures not intended to assess fit. For example, research suggests that assessment center ratings and interviewer judgments are influenced by conscious or unconscious evaluations of applicant fit.

Finally, the *attrition* process refers to the idea that people will leave an organization they do not fit. The turnover literature is quite clear about the fact that people who do not fit an organization will tend to leave it. Of course, economics and job market prospects moderate the extent to which people leave an organization they do not fit. In summary, ASA proposes that three processes—attraction, selection, and attrition—result in organizations containing people with distinct personalities, and it is these distinct personalities that are responsible for the unique structures, processes, and cultures that characterize organizations. Organizational and personal characteristics are self-reinforcing. The characteristics of people in an organization determine the policies and practices, which, in turn, determine the people who are attracted to and remain with the organization.

IMPLICATIONS FOR ORGANIZATIONS

As an outcome of the ASA model, Schneider and colleagues postulated that organizations will become increasingly homogeneous over time. In other words, they will come to be populated by people of a similar personality profile. To assess this hypothesis, Schneider and colleagues examined the personality profiles of approximately 13,000 managers from 142 organizations in the United States. The organizations in their sample represented a broad cross section of industries. Consistent with the homogeneity hypothesis, their results suggested that managers were more similar to managers in their own organization than they were to managers in the other organizations. This remained true when you looked within an industry. That is, even within an industry, managers were more similar to others in their organization than they were to managers in other organizations within their same industry.

Although we previously indicated that there are positive consequences of good fit for people and organizations (regarding satisfaction, commitment, and turnover), the ASA model suggests that the outcome good fit could be detrimental to the long-term viability of an organization, particularly if an organization experiences volatility in its market. The primary negative consequences of good fit or homogeneity are the potential inability for an organization to sense changes in its environment and adapt to those changes and the demise of competitiveness through easily predictable decision making. There is limited research on the consequences of homogeneity for organizational

effectiveness, and the predictions made by the ASA model are complex. For example, the ASA model would predict that during the initial founding and early history of an organization, homogeneity breeds the commitment that is needed to retain people and grow the enterprise. Only after an organization matures and the market becomes more complex and turbulent does homogeneity produce negative consequences. Research does indicate that as the average tenure of the senior managers increases, the fit between the organization's strategy and demands of the business environment decreases. Although not a direct test of the negative consequences of homogeneity, this finding is consistent with the logic of the hypothesis. Additionally, research in social psychology on the effects of homogeneity on group problem solving supports the notion that groups engaged in creative problem-solving tasks do better if they are heterogeneous. The conflict that is created by different perspectives is important in these ill-defined problem-solving situations—situations analogous to the strategic decisions made by top managers. As this research implies, the ASA model predicts that the negative consequences of homogeneity may only manifest themselves at the upper levels of the organizational hierarchy (where managers are faced with strategic decisions). Elsewhere the positive benefits of homogeneity may outweigh the costs.

IMPLICATIONS FOR ORGANIZATIONAL BEHAVIOR THEORY

The ASA model provides an example of multilevel organization theory. Specifically, the psychological attributes of people (in the collective) are hypothesized to be the antecedents of important organizational characteristics. In this way, the ASA model offers a bridge between the micro and macro perspectives. Additionally, the ASA model provides insight into a long-standing argument within psychology—the person–situation debate. This debate seeks to determine which set of attributes (those related to the person, or the situation/environment) are the primary predictors of behavior. The ASA model suggests that the attributes of people shape their environments. The two sets of attributes are not mutually exclusive; rather, they are mutually determined. You cannot separate people from the situation.

AUTOMATION/ADVANCED MANUFACTURING TECHNOLOGY/COMPUTER-BASED INTEGRATED TECHNOLOGY

Automation usually refers to the replacement of human work by machines. The word was first used by the Ford Motor Company in the 1940s to describe automatic handling and machine-feeding devices in their manufacturing processes. *Advanced manufacturing technology* (AMT) is a special instance of automation and usually refers to computer-based manufacturing technologies and support systems. Examples include computerized numerically controlled machine tools, computer-aided design, and computer-supported production control systems. There will be few, if any, manufacturing companies in the developed world that have not undertaken some investment in AMT.

Computer-based integrated technology (CIT) refers to higher levels of integration and comprises systems that cut across organizational functions. For example, enterprise resource planning (ERP) systems include a centralized database and sets of integrated software modules designed to manage all aspects of

an organization's work processes, including production control, customer billing, and human resources. Estimating the uptake of CIT is difficult. However, a survey in Australia, Japan, and the United Kingdom, published in 2002, found that approximately 33% to 40% of larger manufacturing companies (employing more than 250 people) were significant users of CIT. The same survey in Switzerland reported substantial use in around 60% of companies. The findings are similar for ERP systems. By the late 1990s, it was estimated that around 40% of large U.S. companies and 60% of small ones had deployed ERP systems. By 2004, the worldwide market for ERP systems was estimated to be around \$79 billion per annum.

Over the last decade, there has also been growing investment in systems to integrate activities between organizations, a good example being e-business systems that allow electronic ordering and billing through a supply chain and on the part of customers. By the year 2000 it was estimated that around 20% to 25% of companies in the United States, Canada, Europe, and Australia were trading online, although the proportional value of goods traded online was much lower (less than 10%). It is almost certainly the case that these amounts have grown and will continue to grow.

MOTIVES AND IMPACTS

Such investments are usually undertaken for a mix of motives. Machines may do the work more cheaply, more quickly, to a higher quality, with more repeatability, with reduced errors, and with reduced lead times. For these reasons, many companies have become enthusiastic adopters of such new technologies. They are also mindful that if they don't innovate, their competitors might, thereby gaining a significant advantage in the marketplace. This can feed so-called fads and fashions, often vigorously supported by an active community of suppliers of equipment and expertise, including consultants.

Unsurprisingly, such changes are also often accompanied by fears on the part of employees. Will the adoption of new technology lead to reduced headcount and thereby redundancy? Will the remaining jobs become deskilled, with previously skilled employees being reduced to unskilled labor?

It is certainly the case that the trend to automation can reduce headcount. To give a specific example, the city of Sheffield in the United Kingdom, famous for

its high-quality steel, produces the same amount as it ever did in its postwar prime, but now with 10% of the earlier workforce.

But at the same time, the development of computers and their increasing application to different domains has spawned whole new industries, thereby creating many new jobs. New organizations have grown up around the development, provision, marketing, and support of computer hardware and software, project management, knowledge management, computer simulations, software games and entertainment, and communications, to name just some—all enabled by the onset of sophisticated computerization.

Concerns over deskilling are equally complicated to assess in practice. Whereas some organizations have used computer-based operations to deskill their operators—for example, by turning them into machine minders—many others have upskilled their operations by asking their machine operators to write and edit computer programs and to solve complex machine problems. Also, as previously implied, at a more macro level, the onset of computerization has led to the creation of many new highly skilled professions.

The process is further complicated by the onset of globalization. Computer-based information and communications technologies now make it possible to move work around the world. A topical example is provided by the widespread use of customer call centers based in India. This may be to the benefit of the Indian economy, but it may not be perceived that way by employees in the developed world who see their jobs as being exported to regions where labor costs are significantly lower.

Three generalizations seem appropriate. First, such periods of change may be genuinely uncomfortable and threatening for the individuals concerned. It may be no real consolation in losing one's job to be told it is an inevitable long-term structural shift in the nature of the global economy. Second, such changes are likely to be easier to manage and endure during periods of economic growth rather than decline. A buoyant labor market certainly helps. And third, this is one of the reasons why most leading commentators in developed economies see their economic future in the development of highly skilled, high value-added, and highly innovative work, areas where education and skills are at a premium and where competition in a global economy is not solely dependent on the cost of labor.

EFFECTIVENESS AND THE ROLE OF INDUSTRIAL/ORGANIZATIONAL PSYCHOLOGY

The foregoing description gives the impression of inevitability and, although difficult perhaps for some individuals in the short term, of benign and effective progress. However, the position on the ground is a good deal more complex. Let us look now at some of the data on the effectiveness of such new technologies.

The data from economic analyses, surveys, case studies, and expert panels is consistently disappointing. Turning first to ERP systems, many are scrapped (estimates vary between 20% and 50%), and overall failure rates are high (again, estimates vary, at around 60% to 90%). Indeed, it is now commonplace for economists to bemoan the lack of impact of investments in IT (information technology) on overall productivity over time.

The best estimate is probably that up to 20% of investments are true successes, genuinely meeting their goals; around 40% are partial successes, meeting some of their goals but by no means all; and around 40% are complete failures.

So, why are such investments often so disappointing, and what can be done about it? Many industrial/organizational psychologists have worked in this domain, most notably perhaps under the general banner of sociotechnical thinking. Their central proposition is that work systems comprise both technical and social systems and that companies cannot change one without affecting the other—it is the nature of systems that they are intrinsically interconnected. It follows that technical change requires active consideration to changes in working practices and processes, job designs and work organization, employee skills and competencies, training and education, human-computer interfaces, and the management of change. These are major issues, and the evidence is that many organizations focus too much on the technology, pay too little regard to the social, and fail to adopt an integrated systems perspective.

Several attempts have been made at formulating good practice guidelines, of which the following are representative:

- Senior managers should ensure that new technology investments meet the needs of the business. Senior managers should ask, “Why are we doing this? What benefit do we gain? Does it further our strategy?”
- Any technical change will require changes in business processes, working practices, job design, and

the like. Senior managers need to ensure that changes in all these areas are an intrinsic part of the project—a systems view is needed.

- Senior users in the business need to have some ownership of, and influence over, the nature of the changes they require. Changes in systems that are *pulled into* a business are usually much more successful than changes that are *pushed into* a business. Beware projects that seem just to be about IT and that are being pushed hard by the IT department.
- Any project team needs to include all the requisite skills and expertise, including the human and organizational issues.
- The users (or recipients) of any change program need to be actively involved. This should be all the way from the design of the new way of working through to evaluation of the effectiveness of the changes.
- There is a need to educate all those involved in what the changes mean, why they are being undertaken, what benefits accrue, and what actions are necessary to achieve success. At the same time, training is needed on the operational and more detailed aspects of the changes.
- Where such changes are undertaken, organizations need to learn as they go, to be pragmatic, and, where possible, to undertake changes in manageable chunks.
- Evaluation against objectives using benchmark measures is a prerequisite for learning. Internal and external benchmarking can provide excellent opportunities for improvement.
- All the above require the commitment of resources, in particular time, effort, money, and expertise. They also require a different mind-set on the nature of change, one that adopts a systems orientation and views technology as a necessary but not sufficient predictor of success.

These guidelines may seem relatively unsurprising to students of industrial/organizational psychology.

But there continues to be evidence that such standards are ignored in practice. Perhaps the interesting question is, “Why is it that informational technology failures persist?” There is massive potential here for industrial/organizational psychologists to make a substantial contribution, but it is likely that this will best be achieved by working with other disciplines (including technical and operational specialists) and with organizations facing some very practical problems. It is certainly true that we need to bridge the divides between disciplines and between academia and practice.

B

BALANCED SCORECARD

Balanced scorecard is a management system that enables organizations to translate vision and strategy into action. This system provides feedback on internal business processes and external outcomes to continually improve organizational performance and results. Robert Kaplan and David Norton created the balanced scorecard approach in the early 1990s.

Most traditional management systems focus on the financial performance of an organization. According to those who support the balanced scorecard, the financial approach is unbalanced and has major limitations:

- Financial data typically reflect an organization's past performance. Therefore, they may not accurately represent the current state of the organization or what is likely to happen to the organization in the future.
- It is not uncommon for the current market value of an organization to exceed the market value of its assets. There are financial ratios that reflect the value of a company's assets relative to its market value. The difference between the market value of an organization and the current market value of the organization's assets is often referred to as intangible assets. Traditional financial measures do not cover these intangible assets.

The balanced scorecard suggests that organizations should be viewed and measured from four different perspectives. These perspectives are as follows:

- **The business process perspective**—the internal business processes that are often classified as

mission oriented and support oriented. Examples of this perspective include the length of time spent prospecting and the amount of rework required.

- **The customer perspective**—the level of customer focus and customer satisfaction. Examples of this perspective include the amount of time spent on customer calls and customer survey data.
- **The financial perspective**—the financial aspects of the organization. Examples of this perspective include financial ratios and various cash flow measures.
- **The learning and growth perspective**—includes employee training and organizational attitudes related to both employee and organizational improvement. Examples of this perspective include the amount of revenue that comes from new ideas and measures of the types and length of time spent training staff.

Using the balanced scorecard, companies create their own unique measures of these four aspects of the business. The specific measures that a company develops should reflect the specific drivers and strategy of the business.

Kaplan and Norton recommend a nine-step process for creating and implementing the balanced scorecard in an organization.

1. Perform an overall organizational assessment.
2. Identify strategic themes.
3. Define perspectives and strategic objectives.
4. Develop a strategy map.
5. Drive performance metrics.
6. Refine and prioritize strategic initiatives.
7. Automate and communicate.

8. Implement the balanced scorecard throughout the organization.
9. Collect data, evaluate, and revise.

There are many benefits and challenges to the balanced scorecard. The primary benefit is that it helps organizations translate strategy into action. By defining and communicating performance metrics related to the overall strategy of the company, the balanced scorecard makes the strategy come alive. It also enables employees at all levels of the organization to focus on important business drivers.

The main challenge of this system is that it can be difficult and time-consuming to implement. Kaplan and Norton originally estimated that it would take an organization a little more than 2 years to fully implement the system throughout the organization. Some organizations implement in less time and some require more time. The bottom line is that the balanced scorecard requires a sustained, long-term commitment at all levels in the organization for it to be effective.

BANDING

Banding refers to the procedure of grouping test scores into ranges and treating scores within a particular

range as equivalent when making personnel decisions. After an organization collects test scores from candidates who applied for a job, a hiring decision must be made using these scores. There are a number of approaches for making these decisions. One common strategy is called *top-down selection*: Candidate scores are ranked from highest to lowest and organizations start at the top of the list by selecting the candidate with the highest score, then move to the person with the next highest score, and so on down the list. Another common strategy is the practice of setting cutoff scores. A cutoff score involves setting a passing score where candidates at or above this score are labeled as passing the test, whereas those below are labeled as failing. With a cutoff score those passing are treated as if they performed equally on the test. Banding is an alternative to top-down and cutoff score approaches.

Banding involves creating a defined range within which candidate scores are treated as being the same. This is similar to grouping scores into grades as done in many academic settings (e.g., a score between 90% and 100% is considered an A, a score between 80% and 89% is considered a B, etc.). The concept of banding is based on the idea that small differences between test scores may not translate into meaningful differences in expected job performance. For example, a candidate who scores 94% on a test may not perform noticeably better on the job than a candidate who scores 92%. This is because tests are not perfectly predictive of job performance and have varying degrees of measurement error. Banding is the idea of taking into account this imprecision by creating ranges within which test scores are treated as being the same. Thus for candidates who have scores that fall within the same band, the difference between their scores is viewed as meaningless in terms of predicting meaningful differences in job performance, and therefore the candidates are treated as if they scored equivalently on the test.

PURPOSE OF BANDING

One key question is, Why would an organization create bands within which candidate scores are considered equivalent? Critics have argued that banding results in a loss of information and has a negative impact on the utility or usefulness of a test. They state that a top-down approach has the highest utility. In response others have noted that although banding may

in some circumstances result in a loss of economic utility, this loss may be negligible and must be weighed against other compelling reasons for banding such as the need to increase workforce diversity.

Banding was first proposed as a method for reducing the adverse impact against protected groups (e.g., minorities, women) that is often associated with a top-down approach to selection test decision making. This is because Whites, on average, tend to outperform certain minorities on commonly used written multiple-choice selection tests measuring factors such as cognitive ability and job knowledge. Given this situation, Whites will be chosen at a substantially higher rate in comparison to members of these minority groups if a strict top-down rank order approach is used. Banding was suggested as a viable strategy for addressing this problem. Banding can reduce adverse impact because a band includes lower-scoring as well as higher-scoring individuals; thus when selection decisions are made regarding whom to choose from a band, other factors such as diversity can be taken into account. That is, if candidates that fall within a band are considered equal, an organization may consider the minority group membership of candidates when deciding whom to hire from a given band rather than just selecting the individual with the highest score. Banding allows an organization the flexibility to consider other factors such as diversity when making hiring decisions, whereas a top-down approach does not.

CREATING BANDS

Many different methods exist for developing bands. For example, expert or managerial judgments could be used to determine what range of scores on a test should be considered equivalent. Another viable approach is to use historical data on how candidates in the past performed on the test and subsequently on the job to determine what bands should be formed. An additional, yet controversial, method for creating bands is the concept of using indicators test reliability as a basis for creating bands. This approach uses statistical significance testing to determine what size the band should be so that test scores that fall within a band are not considered statistically different.

The most common version of this approach leverages a statistic known as the standard error of the difference (SED) to create bands. This SED procedure specifies a range of test scores that will be treated as statistically indistinguishable at some accepted level

of confidence. That is, the bandwidth is a function of the standard error of measurement of the test and the desired level of confidence that scores within a band are not statistically different. This approach leverages the psychometric properties of the test in terms of its reliability to determine proper bandwidth. Critics of this approach state that the logic behind it is fatally flawed and that carrying it out to its conclusion would lead to random selection (i.e., selecting individuals completely at random rather than based on their test scores). However, proponents of this approach note that because selection tests are not perfectly reliable, the degree of unreliability should be taken into account when interpreting test scores. They further state that using indicators of unreliability is a more objective and appropriate way to create bands than doing so based on purely arbitrary decisions or solely relying on *expert* judgments.

TYPES OF BANDS

Bands can be either fixed or sliding. Fixed bands use the top score as the starting point, and the first band consists of all scores that fit within the range of the top score minus the bandwidth. For example, if the top score on a test was 96.0 and the bandwidth based on the SED approach was 5.2, the first band would range from 96.0 to 90.8. All scores that fell within this range would be considered part of band one and they would be treated as if they were equivalent. The second band would be the next highest score after band one minus the bandwidth. Therefore, for the example given earlier, the second band would range from 90.7 to 85.5. Additional bands would be created in a similar manner. With a fixed band approach, all individuals within a given band must be selected prior to moving to the next band. That is, band one needs to be completely exhausted before moving to band two.

Sliding bands also use the top score as an initial starting point, and the band is equal to this starting point minus the bandwidth. However, the difference with sliding bands is that when the top score is selected, a new band is formed using the next highest existing score in the band as the starting point. That is, when a top score in a band is chosen, the band slides down and is established using the next highest score as its anchor point. Using the previous example where the top score was 96.0 and the bandwidth was 5.2, individuals would be chosen from within this band until the top score is chosen, at which time the band

would slide down to be anchored on the next highest score. Thus if the individual with a score of 96.0 was chosen and the next highest score was 94.0, the new band would be set at 94.0 minus the bandwidth of 5.2 (i.e., a range of 94.0 to 88.8). Furthermore, when the current high score of 94.0 is chosen, the band would slide again and anchor on the next highest remaining score. The sliding band allows an organization to consider more people more quickly by moving down the rank order list more rapidly. Unlike with fixed bands, sliding bands do not require that a band be exhausted before moving down the list. Instead, when a top score is chosen, the band slides down and allows the organization to consider new individuals for selection.

EFFECTIVENESS AND LEGALITY OF BANDING

Research has shown that depending on varying circumstances, such as bandwidth size, banding can be used to reduce adverse impact. An organization can use banding procedures to group scores and then give preference to certain groups when selecting from a band as a means of increasing the diversity of its workforce. Opponents of banding note the loss in utility from not using a top-down approach, but proponents have responded by stating that the possible loss in economic utility is not substantial. One other key issue is whether banding is a legal practice. Most agree that although banding is legal, choosing individuals from a band based on protected group status (e.g., race, gender) could be problematic. The Civil Rights Act prohibits considering factors such as race and gender when making hiring decisions. Although this issue has not been fully resolved, recent court rulings have upheld the use of different types of banding. However, a review of these cases indicates that when protected group status is the only factor used to make choices from a band, it is less likely to be acceptable to the courts than when it is only one of many factors that are used.

BEHAVIORAL APPROACH TO LEADERSHIP

The behavioral approach to leadership involves attempts to measure the categories of behavior that are characteristic of effective leaders. Two research projects, one at Ohio State University and another at the University of Michigan, are most commonly associated with the behavioral approach to leadership. The results of both research programs suggested that the behavior of effective leaders could be classified into two general categories. The behavioral approach dominated leadership research throughout most of the 1950s and 1960s.

THE OHIO STATE STUDIES

Immediately following World War II, a group of scholars, including Carroll L. Shartle, John K. Hemphill, and Ralph M. Stogdill, conducted a series of investigations that became known as the Ohio State Leadership Studies. Rather than focusing on the traits or styles of effective leaders, as had been the focus of much early psychological research on leadership, these researchers studied the behaviors that leaders engaged in during the course of their interactions with followers. In a review of early leadership research, Stogdill (1963) declared that attempts to discover the traits shared by effective leaders had largely failed. This presumed failure, coupled with the rise of the behaviorist school of psychology, which emphasized behaviors rather than personality or mental processes, helped prompt the abandonment of trait-oriented leadership research and the rise of the behavioral approach.

Using detailed observations of leaders' behaviors, as well as reports from the leaders themselves and

from their subordinates, the Ohio State researchers accumulated a list of hundreds of leader behaviors. From these a list of 150 statements was derived that represented unique leader behaviors, such as “He assigns group members to particular tasks” and “He finds time to listen to group members.” These 150 items composed the first form of the Leader Behavior Description Questionnaire (LBDQ). The LBDQ was administered to workers who rated how often their leaders engaged in each of the behaviors, using a five-point scale from *never* to *always*.

The responses to these items were subjected to factor analysis. The results suggested that the various leader behaviors clustered into one of two factors or categories: initiation of structure and consideration. Initiation of structure includes leader behaviors that define, organize, or structure the work situation. For example, clearly defining roles, assigning specific tasks, communicating work-related expectations, emphasis on meeting deadlines, maintaining standards of work performance, and making task-related decisions are all examples of initiation of structure behaviors. The orientation of these initiation of structure behaviors is focused primarily on the work task.

Consideration behaviors are those where leaders show concern for the feelings, attitudes, needs, and input of followers. They include the leader developing rapport with followers, treating them as equals, showing appreciation for their good work, demonstrating trust in followers, bolstering their self-esteem, and consulting with them about important decisions. The considerate leader is concerned with follower job satisfaction and with developing good interpersonal relationships with and among members of the work group.

The Ohio State researchers concluded that these two leadership behavior dimensions, initiation of structure and consideration, were not opposite ends of a continuum. They were independent of each other. In other words, both were independently related to effective leadership. They found that some effective leaders displayed high levels of initiation of structure behaviors, others engaged in high levels of consideration behaviors, and some displayed high levels of both. Only low incidences of both initiation of structure and consideration behaviors were associated with ineffective leadership.

The two dimensions of initiation of structure and consideration struck a responsive chord with leadership scholars, and a great deal of research followed. One line of research examined the robustness of the

initiation of structure and consideration dimensions. Those results were generally supportive, suggesting that most leader behavior can indeed be grouped into one of the two general categories.

Research also refined the LBDQ. It was first reduced to 40 items, and a special version, the Supervisory Behavior Description Questionnaire, was constructed to measure the behavior of lower-level managers. A final revision yielded the LBDQ–Form XII, consisting of 10 items measuring initiation of structure and 10 items measuring consideration. The LBDQ–XII is the most widely used in research and is still readily available to scholars.

Additional research investigated the relationship between the two categories of leader behavior and work outcomes. For example, initiation of structure was found to correlate positively with effective group performance, but the relationship between initiation of structure and group member job satisfaction is less clear. There is some evidence for a positive relationship, but some conflicting evidence suggests a possible negative correlation between initiation of structure and job satisfaction, with a corresponding increase in employee turnover. Conversely, leader consideration was found to correlate positively with follower job satisfaction, but there have been inconsistent findings regarding work group performance. Correlations between leader consideration and performance have ranged from slightly positive to slightly negative.

These inconsistent results led researchers to conclude that the effectiveness of these broad categories of initiation of structure and consideration leader behaviors was likely dependent on contingencies in the leadership situation. Factors such as the type of work task, the structure of the work group and organization, the size of the group, and the level of the leader (e.g., executive versus middle manager versus front-line supervisor) can all influence how initiation of structure and consideration relate to key outcomes such as group performance and satisfaction.

THE UNIVERSITY OF MICHIGAN STUDIES

About the same time as the Ohio State studies, researchers at the University of Michigan, including Rensis Likert, Robert L. Kahn, Daniel Katz, Dorwin Cartwright, and others were also focusing on leader behaviors, studying leaders in several large, industrial organizations. They reached a conclusion similar to

the one reached by the Ohio State researchers. Leader behavior could indeed be clustered into two broad categories. The Michigan State researchers distinguished between task-oriented (also referred to as *production-oriented*) and relationship-oriented (also referred to as *employee-oriented*) leader behaviors.

Task-oriented leader behaviors tend to focus on performing the work group's job and are similar to initiation of structure behaviors. Task-oriented behaviors include setting clear work standards, directing followers' activities, instructing them on work procedures, and meeting production goals. Relationship-oriented behaviors focus more on employee well-being and allowing them to participate in decision-making processes, similar to consideration behaviors. The main difference between the Ohio State and the University of Michigan approaches was that the Michigan results suggested that relationship-oriented leader behaviors were more effective overall than task-oriented behaviors, but both types of leader behaviors were displayed by the most highly effective leaders. This makes intuitive sense considering research findings that suggest stronger connections between task-oriented leader behaviors and group performance and relationship-oriented behaviors and follower satisfaction, rather than vice versa. Therefore leaders who are both task and relationship oriented should turn out workers who are *both* productive and satisfied.

This notion influenced the development of the Leadership Grid, a leadership intervention program designed to foster both task- and relationship-focused leader behaviors. In the Leadership Grid, leaders are taught to be concerned with both production and people. Leaders who demonstrate both categories of leader behavior are seen as *team leaders*, whereas those who lack both are considered *impoverished*.

CONTRIBUTIONS AND LIMITATIONS OF THE BEHAVIORAL APPROACH

The main contribution of the behavioral approach to leadership is the explication of two very different forms of leader behavior: those that focus on the work task and those that focus on the follower. The fact that two independent lines of research arrived at the same two general categories suggests that these factors are clear and distinct.

The primary limitation of the behavioral approach was suggested by the research findings. How could such very different forms of leader behavior—focusing

on the task, versus focusing on the people—both lead to effective leadership in some cases but not in others? The answer is that elements of the situation interact with styles of leader behavior to determine when the two categories of leader behavior might be effective and when they are not. This led to the development of contingency, or situational models, of leadership that examined the interaction between leader behavior and styles and variables in the situation that facilitate effective leadership. Although the situational theories of leadership go beyond the simple focus on leader behavior, most incorporate the results of the behavioral approach as an important element of their models.

BENCHMARKING

Organizations use a variety of measurements to evaluate business performance, such as revenue, stock price, voluntary attrition, or employee attitude survey results. Comparing these measures to relevant

benchmarks provides decision makers with a standard that can be used to interpret the organization's standing and draw meaningful conclusions. The standard, target, or benchmark can be derived from internal organizational data or from data external to the organization. Benchmarking databases are similar to normative data used in clinical psychological testing to establish parameters for normal and abnormal results. Although benchmarking commonly uses numeric data for comparisons, nonnumeric benchmarking is also used to aid decision making, in areas such as strategic organizational direction, or in processes such as supply chain or marketing. The benefits, caveats, and sources of benchmarking are addressed in the following text.

BENEFITS

The benefits of benchmarks are to provide an empirically substantiated target figure that is more realistic and has more credibility and weight than one determined subjectively, such as *gut feeling*. Targets created in an internal vacuum may result in setting goals that are neither challenging enough nor attainable. Research has shown that these types of goals are de-motivating. Although benchmarks based on internal organizational data can be constructed, external benchmarks, especially when competitors are involved, have gravitas that usually gets the attention of executives who make strategic decisions regarding an organization's future direction and can serve to inspire positive changes. In addition, benchmarking allows *best practices* to be identified: approaches yielding results surpassing all others.

CAVEATS

There are a number of caveats regarding external benchmarking. Some benchmark databases are composed of samples of convenience that may contain comparison groups that are neither relevant nor equivalent, thus making differences between an organization's scores and the benchmark of little or no value. Other benchmark databases may be of questionable quality. These types of poorly constructed benchmarks again can result in setting de-motivating goals that are either unrealistic or not challenging enough. Similar to the need for norm groups that are representative of the population of interest in interpreting scores on clinical psychology tests (e.g., matched on salient demographics; excluding those with impairments), comparable

organizations, such as same industry and similar size, are best for benchmarking purposes in a business setting. However, it is important to keep in mind that even organizations in quite different industries may be similar on other dimensions such as competition to recruit the same top employee talent. In this case obtaining external benchmarks on such things as workplace climate provides a context for evaluating an organization's position as an employer of choice.

Economic and cultural differences are also important to consider and control for to develop appropriate business benchmarks. For example, comparing business results in countries in emerging economies to results in countries with more established economies is not a useful comparison. An additional example comes from employee opinion research where it is widely known that employees in some countries typically have more positive responses compared with employees in other countries. If these responses are pooled across all countries, an organization with representation in countries with typically less favorable responses will be compared with a database skewed in a more positive direction.

In addition, comparability of question translations across companies that contribute data to a benchmark database needs to be considered when evaluating benchmarks for global employee opinion surveys. For example, two different question translations may result in different interpretations of the question, thus producing poor-quality benchmarks. Some consortia attempt to solve this problem by establishing common translations that organizations must use to submit data to the benchmarking database.

INTERNAL BENCHMARKING

Internal comparisons can avoid some criticisms applied to external benchmarking. Types of internal benchmarking include tracking trends over time, polling executives to set goals, or identifying perceived gaps between executives' expectations and the current state in an organization. However, in the absence of external values, it can be difficult to determine reasonable targets for an outcome or strategic direction. That is, internal improvements over time may not be enough if results remain below par compared with competitors. Further, internal benchmarks across different units within a single organization can promote unhealthy internal competition versus all internal efforts being directed at external competitors.

Internal improvements also may reach a ceiling, a numeric level that is typically not exceeded. For example, in workplace climate research the best achievable score for employee satisfaction with compensation is routinely much lower than the best achievable score for satisfaction with organizational teamwork. Without external benchmarks, these *ceiling* differences would be unknown, and unrealistic targets for improvement could be set.

BENCHMARKING SOURCES

Sources of external benchmarks include nonprofit consortia. Consortia typically collect a fee, have rigorous standards for company membership and data contributions, and a hire a third party vendor to collect data and provide reports to members. Consortia have additional benefits in terms of cross-company information sharing, networking, and standardization of instruments for collecting the data submitted to the benchmarking database. Well-known consortia exist in the life insurance and banking or financial industries. Others focus on specific metrics such as employee opinion survey research.

Consultants may also provide benchmarking data to clients using their client base as the source. Benchmarking data may also be available via public information sources, such as financials for publicly traded companies.

The list of organizations included in the database—their size, the number of data points from each organization, the countries from which the data originate, and the time frame in which the data were collected—are all important questions to ask the provider when evaluating benchmark data.

SUMMARY

External and internal benchmarking are extremely valuable organizational tools that potentially provide appropriate targets and direction for actions that can contribute to greater success in an organization. Recognizing the limitations and applications of benchmarking and benchmarking sources will avoid obtaining inaccurate data that may lead to misinformed decision making and ill-directed corporate strategizing.

BIG FIVE TAXONOMY OF PERSONALITY

Personality traits are characteristic behaviors, thoughts, and feelings of an individual that tend to occur across diverse situations and are relatively stable over time. Given this broad definition, literally thousands of personality traits can be identified. For the better part of 100 years, personality researchers have attempted to create a standard taxonomy, or organizing structure, of personality traits. Although some disagreement remains, the Big Five taxonomy is currently the dominant perspective on the organization of personality traits. The Big Five traits are identified in the following text, and trait descriptive terms are provided for each:

1. **Neuroticism:** Anxious, temperamental, nervous, moody versus confident, relaxed, unexcitable
2. **Extraversion:** Sociable, energetic, active, assertive versus shy, reserved, withdrawn, unadventurous
3. **Openness:** Intellectual, innovative, artistic, complex versus unimaginative, simple, unsophisticated
4. **Agreeableness:** Trusting, trustful, helpful, generous versus cold, harsh, rude, unsympathetic
5. **Conscientiousness:** Organized, neat, thorough, systematic, efficient versus careless, undependable, haphazard, sloppy

The term *Big Five* was coined by Lewis R. Goldberg in 1981 and was meant to signify that these traits are

broad in nature. Generally, the Big Five trait taxonomy is conceptualized as hierarchical, such that the Big Five traits are the broadest level. Within each of the Big Five traits, narrower trait dimensions can be defined, representing the second level of the hierarchy. As one progresses to lower points in the hierarchy, increasingly narrow trait dimensions can be identified. The lowest level of the taxonomy consists of specific behaviors.

ORIGINS OF THE BIG FIVE

Although human curiosity and examination of personality traits dates back to the ancient Greeks, the history of the Big Five begins with the work of Gordon W. Allport and Henry S. Odbert based on the lexical hypothesis. The lexical hypothesis suggests that important aspects of human behavior will be encoded into language; and the more important an aspect is, the more likely it will be encoded as a single word. Based on this hypothesis, Allport and Odbert turned to the dictionary to identify the basic elements of personality. They identified almost 18,000 personality related words, and organized these terms into four categories:

1. personal traits,
2. temporary moods,
3. evaluative terms (such as excellent or irritating), and
4. miscellaneous.

Although Allport and Odbert stopped with the identification of these personality descriptive terms, Raymond B. Cattell sought to bring order to them. Cattell began his work with the set of nearly 4,500 words Allport and Odbert placed in the personal trait category. As this set of terms was far too large to investigate empirically, Cattell conceptually combined the terms into 171 clusters. Still too numerous to work with given that his computations needed to be done by hand, he eventually worked his way down to a set of 35 clusters. He was then able to collect data on these clusters and conduct a factor analysis. Finally, he arrived at a set of 12 factors, but many believe that he overfactored the data.

Based on Cattell's work, two factor-analytic studies provided a foundation for what would eventually become the Big Five. Using 22 of Cattell's 35 clusters, Donald W. Fiske in 1949 and Ernest C. Tupes and Raymond E. Christal (1961/1992) found five

similar factors when scores from the 22 clusters were factor analyzed. The Tupes and Christal findings were particularly interesting in that they found the five factors within each of eight samples that differed in many ways: education (high school graduates, college students, graduate students), type of rating (self-ratings, peer ratings), and among the peer ratings, length of acquaintanceship (from 3 days to 1 year or more). The five factors identified by Fiske and by Tupes and Christal were defined in a manner that is similar to the way in which the Big Five are defined today.

Recognizing some of the limitations in Cattell's conceptual sorting of the trait terms, Warren T. Norman went back to the beginning and developed a new list of trait descriptive terms from the dictionary. Norman, like Allport and Odbert before him, sorted his set of terms into broad categories and focused his work on those terms that fell into the category he labeled biophysical traits. After doing considerable work to reduce the set of terms in this category to roughly 1,550 terms, he set out to organize them. First, the terms were sorted into the endpoints of the five factors identified by Tupes and Christal, giving him 10 groups of words. He then sorted each of the 10 groups of words, which resulted in 75 groups of words. A factor analysis of scores on these groups produced the expected five factors.

To this point, much of the research on the five factors had been directly related to the initial work of Cattell. Recognizing this fact, Goldberg (1990) conducted studies on trait terms that were common in the English language, finding the same five-factor structure. Given that these words were selected on the basis of common usage and not on the variables identified by Cattell, these studies demonstrated that the five factors were general and not specific to Cattell's variables. The Big Five was born.

To date, considerable research has been conducted to establish the Big Five. Numerous questionnaire measures of the Big Five traits have been developed, suggesting that the factors are not unique to the study of trait descriptive terms. The five factors have been found in a wide variety of cultures from across the globe in both adjective and questionnaire measures; and evidence suggests that they are, at least in part, heritable.

LINGERING TAXONOMIC ISSUES

Although the Big Five is the dominant perspective on the organization of personality traits, there remain

differences of opinion regarding some aspects of the taxonomy. Hans Eysenck (1992) and Auke Tellegen, for example, have argued that the highest level of the taxonomy should be represented by three rather than five traits. Eysenck has vigorously defended his position that the highest level of the taxonomy should be represented by the traits of extraversion, neuroticism, and psychoticism, a perspective that some have referred to as the *Even Bigger Three*. Although extraversion and neuroticism are defined by Eysenck in a manner that is consistent with the Big Five, he argues that psychoticism is made up of lower levels of conscientiousness and agreeableness. Tellegen has taken a position similar to Eysenck's, arguing that the three traits of positive emotionality (extraversion and part of conscientiousness), negative emotionality (neuroticism and low agreeableness), and constraint (part of conscientiousness and low openness) should dominate the highest levels of the trait taxonomy.

Some debate also remains about the names and definitions of some of the Big Five traits themselves. For example, the agreeableness dimension has also been referred to as love, likability, and nurturance, each of which conveys a somewhat different interpretation. Oliver John has argued, in fact, that the term *agreeableness* is somewhat misleading, suggesting a submissive nature that would actually be located at the lower end of the extraversion trait. Although the term *conscientiousness* seems to be well accepted at this point in time, this trait has also been referred to by various authors as dependability, work, will to achieve, responsibility, and constraint. Perhaps the most controversy, however, has surrounded the nature of the openness dimension. In addition to openness, this dimension has been referred to as culture, intellect, and intellectance. The controversy stems from the apparent incorporation of aspects of intelligence into the factor. For example, in Goldberg's work, the term *intelligent* was consistently an indicator of this dimension. Some researchers have been highly critical of the association of this dimension with intelligence, fearing that the dimension will be considered synonymous with intelligence as measured by IQ tests when, in fact, the dimension is much broader, encompassing artistic and creative aspects, a willingness to try new things, and a sense of open-mindedness.

It seems that much of the controversy surrounding the naming of the five dimensions is a result of their broad nature. Some clarity might be brought to the

issue if there were to be consensus regarding the next lowest level of the trait hierarchy. Scant work, however, has been done to identify and define the traits at the level below the five dimensions. There is some consensus among industrial/organizational (I/O) researchers interested in personality that the trait of conscientiousness can be broken down into two dimensions of achievement striving and dependability. Also, Robert and Joyce Hogan have argued that extraversion can be split into sociability and ambition. It seems clear that research focusing explicitly on this level of the hierarchy is warranted.

One problem with establishing the lower levels of the trait hierarchy is that the hierarchy is likely to be reticulated. That is, many lower-level traits are liable to relate to more than one trait at the higher levels. Using studies of adjectives as a source of examples, some researchers have associated warmth with extraversion whereas others have associated it with agreeableness. Likewise, the characteristic of impulsiveness has been associated with neuroticism, extraversion, and conscientiousness by various researchers. These cross-associations of traits at one level with traits at higher levels will make the process of achieving consensus at levels of traits below the Big Five difficult, but it would seem to be a worthwhile endeavor.

It is important to recognize that the Big Five taxonomy is simply descriptive and is not a theory. As such, it does not explain why people behave in the ways they do; it is only a system for classifying behavioral tendencies. Although many have criticized the Big Five because it is not theoretical, others have argued that the taxonomy is necessary before theory can be developed. To this end, Paul Costa and Robert McCrea have proposed a five-factor theory of personality. Although the theory is broad in scope, at its core it suggests that the Big Five are a result of biological processes and influence people's characteristic adaptations—the ways they think, feel, and behave in their unique environments.

THE BIG FIVE AND INDUSTRIAL/ ORGANIZATIONAL PSYCHOLOGY

The emergence of the Big Five through the 1980s was a tremendous benefit to both I/O-related research and the application of personality testing in organizational contexts. Although multitrait personality inventories began to emerge in the 1930s, the use of personality testing in applied settings was largely haphazard and

not theoretically grounded before the emergence of the Big Five. Reviews of the criterion-related validities of personality scales conducted in the 1950s suggested little support for using personality tests for predicting job performance. As noted by Robert Guion and Richard Gottier in 1965, the field seemed to be dominated by a *broadside* approach where every available personality test score was correlated with all available performance measures. Although many of the observed correlations were small, Guion and Gottier asserted that many of these would be expected, based on theory, to be small.

The emergence of the Big Five allowed researchers and practitioners to select traits (and scales representing those traits) based on a conceptual mapping of the traits to the performance dimension. As a result, numerous meta-analyses on the relationships between personality test scores and measures of work performance have resulted in positive findings regarding the criterion-related validities of personality tests. These meta-analyses have generally shown that conscientiousness is related to almost all job-related criteria (i.e., performance, training, attendance, etc.) across almost all jobs. Other Big Five dimensions have also proven important predictors but not as universally as conscientiousness. For example, extraversion has been shown to be related to performance in managerial and sales jobs, and openness has been related to training performance.

Having established the usefulness of personality testing, many researchers are exploring factors that may strengthen or weaken the personality–performance relationship. In 1993, for example, Murray Barrick and Michael Mount examined the extent to which the degree of autonomy given to employees would moderate the relationship between conscientiousness and job performance. They found that in autonomous situations (i.e., where workers had more control over their activities), the relationship between conscientiousness and job performance was stronger than in situations where workers were given less autonomy.

One contentious issue has been whether practitioners should use broad or narrow traits to predict performance; that is, whether to focus on the Big Five or on more narrow traits at some point lower in the hierarchy. Although authors on both sides of this issue have made potent arguments for their perspectives, it would appear that the solution is to attempt to match the breadth of the predictor with that of the criterion.

When predicting broad criteria, it appears optimal to use broad traits such as the Big Five. In contrast, when more narrow criteria are of interest, narrower trait constructs are preferred.

CONCLUSIONS

The Big Five trait taxonomy is the dominant organizing structure for personality traits. Although the traits emerged from the lexical approach to personality, the structure is found with questionnaire measures and identified in cultures around the world. The impact of the Big Five on the role of personality in I/O research and application has been immense, allowing for theoretically guided predictor-criterion mapping. At present, there is a great deal of interest in personality within the field of I/O psychology, an interest in no small part a result of the Big Five taxonomy of personality traits.

BIOGRAPHICAL DATA

Biographical data, or biodata, are measures of key aspects of individuals' life experiences intended to predict job applicants' future performance in organizations, whether that performance is task-specific job performance, teamwork, or shoplifting. Although biodata can be developed to measure a wide array of experiences and psychological constructs, the fundamental and general premises underlying the predictive power of biodata measures are that

- individuals in free societies shape their life experiences, and they also are shaped by them;
- this process of reciprocal influence between personality and situations occurs over a large time span; and therefore,
- measures of past experience should predict future work behavior, especially given a relatively unconstrained environment where employees' typical performance can be wide-ranging.

In light of these premises, items on a biodata measure can be relatively personality oriented or covert in nature (e.g., "To what extent does your happiness depend on how things are going at work?"), or they can be relatively situation oriented and overt in nature (e.g., "Approximately how many books have you read in the past three months?"). In either case responding involves some cognitive processing where test takers are required to recall and summarize information, the accuracy of which depends on the accuracy of prior perception and storage, and in many cases the saliency or recency of the event.

Although biodata can vary widely in their content and constructs measured and can be scored in different ways, they have consistently demonstrated moderate to high levels of validity across job types (approximately .30); they also demonstrate incremental validity beyond ability and personality measures in predicting performance. Constituent biodata items either explicitly or implicitly reflect constructs such as ability, personality, motivation, interpersonal skills, and interests. They can be relatively pure measures of these constructs; however, biodata items that ask test

takers about their experiences may be related to a combination of constructs, not just one. Analyses of the latter type of items may result in a weak general factor in a factor analysis or a low alpha reliability coefficient. Both test–retest reliability and alpha reliability should be considered when attempting to measure the stability of scores on biodata measures.

ITEM ATTRIBUTES

An outline of 10 major attributes of biodata items was proposed by F. A. Mael and is as follows:

1. Historical versus hypothetical (past behaviors versus predicted behaviors in the future, or behaviors in *what-if* scenarios)
2. External versus internal (behaviors versus attitudes)
3. Objective versus subjective (observable or countable events versus self-perceptions)
4. Firsthand versus secondhand (self-descriptions versus how people would say others describe them)
5. Discrete versus summative (single events versus averaging over a period of time)
6. Verifiable versus nonverifiable
7. Controllable versus uncontrollable (circumstances that could or could not be influenced by a decision)
8. Equal access versus unequal access (access to opportunities with respect to the group being tested)
9. Job relevant versus nonjob relevant
10. Noninvasive versus invasive

SCORING METHODS

Historically, biodata measures have developed out of a tradition of strong empiricism, and therefore a wide variety of scoring methods have been proposed. The criterion-keying approach involves taking individuals' responses to a given biodata item and calculating the mean criterion score or the criterion-related validity for each response option. This is done for each item, and these values are used as item response weights for scoring purposes. Weights may be rationally adjusted when nonlinear patterns in relatively continuous response options are found or when some weights are based on small sample sizes. A similar approach to criterion keying can be taken when keying biodata items not to criteria but rather to personality or

temperament measures. This is a particularly interesting approach in keying a set of objective or verifiable biodata items, which tend to be less susceptible to faking but often are harder to assign to single psychological constructs. (Even if such keying is not done, it remains helpful to place the biodata measure within a nomological net of cognitive and noncognitive constructs.) When biodata items can be assigned to constructs in a relatively straightforward manner, such as by developing item content around constructs or through an a priori or post hoc subject matter expert (SME) item-sorting procedure, a straightforward scoring of each item along a single underlying continuum may be possible as is done with traditional Likert-scale self-report measures of personality.

Configural scoring is an entirely different approach to scoring biodata items, because it involves grouping individuals into representative profiles of biodata scores. Subgroups are defined, both conceptually and methodologically, as internally consistent yet externally distinct, similar to the interpretation of statistically significant group differences in the analysis of variance. Individuals are often assigned to subgroups based on their similarity to a subgroup mean, such as in *k*-means analysis; or sometimes a set of data is aggregated until the appropriate balance between parsimony and descriptiveness is reached, such as in Ward's method. Subgroup profiles may then be labeled (e.g., *goal-oriented social leaders* or *emotional underachievers*) and then related to relevant external criteria, or profiles of criteria, for purposes such as personnel selection and placement; or subgroup profiles can be used in their own right for training and development.

Two general points regarding the scoring of biodata items are worth noting. First, any appropriate scoring method should be informed by both rational and empirical approaches. Being purely rational or theory based ignores important empirical data that could serve to revise the theoretical underpinnings that generated the biodata items in the first place—or at least it could revise subsequent item-development rules. Conversely, being purely empirical in the absence of a theoretical or conceptual rationale would impede, if not preclude, appropriate item development, item revision, and score use and interpretation. Second, item-scoring methods that are developed on one sample should be cross-validated on an independent sample, such as a holdout sample from the original data set or an entirely different sample. Doing so helps ensure that the

features of the model are generalizable and not sample specific; for example, cross-validation can ensure that increased validity, reduction of group mean differences, or a *cleaned up* exploratory factor analysis result achieved in one sample by selectively reweighting or removing biodata items can then be achieved in an independent sample using the same subset of items, so that the original results (in large part, at least) cannot be attributed to capitalization on chance. The same concern applies to regression models, where least-squares regression weights may capitalize on chance and thus artificially inflate validity. In this case, cross-validation formulas can be applied to the whole sample, to estimate what the shrinkage in validity would be should those weights be applied to an independent sample of the same size.

RACE DIFFERENCES

Because biodata items vary widely in content, no general statement about race differences can be made that is of any use. At a more specific level, however, biodata containing culturally relevant content have demonstrated Black–White subgroup differences in terms of differential item functioning (DIF). Black–White differences in biodata have also been found in the domain of swimming proficiency. Other race differences are likely when the biodata measures are aligned with constructs where it is known that race differences exist, such as general cognitive ability or certain personality traits.

APPLICANT REACTIONS

Meta-analysis indicates that studies using biodata measures generally show a favorability (i.e., job relevance and fairness) rating at about the midpoint of the scale, with measures such as interviews, résumés, and cognitive ability tests showing greater favorability and personal contacts and integrity tests showing less favorability. Although the meta-analytic mean across studies is stable, nontrivial variability in favorability ratings across studies exists; this is likely because of the variety of biodata measures that can be developed. This highlights a consistent theme in the research literature: Biodata measures tend to be viewed more favorably when they are perceived as relevant to the job at hand and part of a fair personnel selection system.

BONA FIDE OCCUPATIONAL QUALIFICATIONS

United States federal fair employment laws generally prohibit discrimination in employment on the basis of certain *protected characteristics*, including race, color, religion, sex, national origin, age, and disability. However, the fair employment laws permit employers to discriminate based on a protected characteristic in rare situations where the characteristic is considered a bona fide occupational qualification (BFOQ) for the job in question.

The BFOQ defense is potentially available in those Title VII cases where it has been established, and not merely alleged, that an employer’s employment policy intentionally discriminated on the basis of religion, sex, or national origin. The BFOQ defense does not apply to discrimination based on race or color. It is also potentially available in cases involving employer

policies that have been shown to intentionally discriminate the basis on age (Age Discrimination in Employment Act) or disability (Americans With Disabilities Act). Where successfully asserted, the BFOQ defense allows employers to treat job applicants or employees differently depending on their protected class status (religion, sex, national origin, age, disability), making permissible conduct that would otherwise be considered illegal discrimination. For example, although Title VII generally prohibits discrimination against job applicants based on their sex, if it is established that being male is a BFOQ for the job in question, the employer may lawfully refuse to consider women for the job. However, it is important to understand that the BFOQ defense is narrowly written and extremely narrowly construed by the courts and that employers asserting the defense have the burden of proving that its stringent requirements (discussed in the following text) are met. As a result, the BFOQ defense is available in relatively few situations.

REQUIRED ELEMENTS OF THE BFOQ DEFENSE

To establish a BFOQ, an employer must meet two requirements. First, the employer must prove that a strong, direct relationship exists between the protected characteristic in question (e.g., sex) and an employee’s ability to perform one or more functions of the job in question. Second, the employer must prove that the functions of the job to which the protected characteristic is directly related are important functions that go to the *essence* or *central mission* of the employer’s business operation.

The Direct Relationship Requirement

The direct relationship requirement must be met by showing either that *all or substantially all* members of the group that is being excluded based on a protected characteristic cannot perform the functions of the job, or that it is *impossible or highly impractical* to determine on an individual basis whether members of the excluded group can perform the functions of the job. For example, an employer seeking to justify a sex-based BFOQ that would allow it to hire only men must show either that all or substantially all females are unable to perform the functions of the job, or that it would be impossible or highly impractical to assess female applicants’ qualifications to perform the job

functions on an individual basis, for example, through the use selection tests.

It is clear that the *all or substantially all* standard can be met without proof that 100% of the excluded class cannot perform the functions of the job in question. However, it is also clear that the employer must produce credible evidence of a strong relationship between the protected characteristic and the ability to perform the job. Relying on stereotypes about the abilities or disabilities of women, older workers, and so on is insufficient. It is also not enough to merely show that members of the excluded group, on average, tend not to perform the job as well. Further, given the vast and growing array of selection tools that are available to assess job applicant qualifications on an individual basis (e.g., assessments of physical strength, motor skills, cognitive ability), it is extremely difficult for employers to successfully argue that they should be able to use a protected characteristic as a general hiring or promotion criterion because it is *impossible* or *highly impractical* to assess applicants' qualifications on a more individualized basis.

Essence of the Business Requirement

It is not enough to show a direct relationship between the protected characteristic in question and a job function that is only incidentally or marginally related to the employer's business operations. The protected characteristic must be directly related to the ability to perform one or more important job functions that are closely associated with the fundamental purpose(s) of the employer's business. This means that to determine whether an asserted BFOQ is justified, the court must determine the primary purpose(s) or *essence* of the business operation in which the job is embedded.

Cases considering whether safety concerns support the BFOQ defense illustrate how the *essence of the business* requirement affects whether the BFOQ defense is available to employers. Safety concerns may be the basis for a BFOQ but only if the safety concern is indispensable to the particular business at issue. For example, the safety of inmates was found to be a legitimate basis for a sex-based BFOQ applied to the prison guard position, because the safety of inmates goes to the core of a prisons guard's job performance and the essence of the business in which prisons are engaged. In contrast, when considering

whether to exclude female employees of childbearing age from jobs involving exposure to toxic material, the Supreme Court held that concerns about the safety of female employees' unborn children may not be the basis for a BFOQ because the essence of the employer's business was manufacturing batteries, and the fetuses of female employees were neither customers nor third parties for whom safety is essential to the business of manufacturing batteries.

General Guidance

Although the availability of the BFOQ defense is determined on a case-by-case basis, and there is some variation in how lower courts interpret and apply the Supreme Court's rulings in this area, useful guidance for assessing the availability of the BFOQ defense can be provided based on court cases, the legislative history, and EEOC (Equal Employment Opportunity Commission) guidelines. In addition to safety concerns, BFOQs have been recognized based on privacy concerns where, again, those concerns relate to the essence of the employer's business, such as sex-based BFOQs for bathroom attendant and masseur positions. The BFOQ defense has also been recognized when viewed as necessary to ensure the genuineness or authenticity of an employer's business operations. Examples of *authenticity* BFOQs include the use of male and female actors to play male and female roles in theater productions and a restaurant hiring only ethnic chefs where a primary goal of the employer is to maintain an authentic ethnic atmosphere.

The courts have uniformly refused to accept discriminatory customer preferences or biases as a basis for a BFOQ, usually noting that these biases are the type of discrimination that fair employment laws such as Title VII were intended to eliminate. For example, courts have refused to accept the preferences of male customers as a legitimate basis for a BFOQ allowing the hiring of only female flight attendants and have rejected the argument that being male was a BFOQ for an overseas assignment because customers and associates in other countries preferred to do business with men.

Finally, it is well settled that the BFOQ defense cannot be based merely on the incremental or extra cost associated with hiring one protected group versus another. Thus, for example, an employer cannot exclude women from a certain position merely because of concerns that allowing women to occupy the position

(i.e., not restricting the position to men) may result in greater health- or liability-related costs for the employer.

BOREDOM AT WORK

Feeling bored at work is a common complaint; a large percentage of employees feel bored at least occasionally and some feel bored much of the time. Boredom has not been studied extensively, but it has attracted some attention from scholars in diverse disciplines including human factors engineering, psychiatry, sociology, education, criminology, and industrial psychology.

DEFINITIONS OF BOREDOM

Most scholars would agree that boredom is an emotion. It is an unpleasant transient state in which individuals feel an extreme lack of interest in their current activity. Bored individuals find it difficult to keep their attention focused on work and may feel that time is passing very slowly. Boredom is usually accompanied by feelings of restlessness, irritability, and desire to escape or change the situation to a more interesting activity. Boredom has been described as the opposite of enthusiasm or *flow*.

Boredom is also sometimes conceptualized as a personality trait, and some individuals are more likely to experience boredom than others. Scores on the boredom proneness scale are related to measures of state boredom, impulsiveness, sensation seeking, depression, negative affect, aggression, hostility, self-reported physical and psychological symptoms, and job dissatisfaction. The remainder of this entry will focus on boredom as a transient state experienced while working.

CONSEQUENCES AND CAUSES OF BOREDOM AT WORK

The consequences of boredom are thought to be largely negative. Boredom at work has been associated with absence, dissatisfaction, accidents, reduced performance on vigilance tasks, performance variability, horseplay, and sabotage. However, it has been suggested that boredom has the potential to stimulate creativity and organizational citizenship behaviors in some cases.

There are many likely causes of boredom at work. These include aspects of work tasks, aspects of the surrounding work environment, and interactions of the task and performer.

Work Tasks

As an emotion, boredom depends on an appraisal of a situation by the performer. Thus boredom does not automatically reside in characteristics of work tasks but in how these tasks are appraised by the individual performing them. Nevertheless, there are types of tasks that are likely experienced as boring by most people. What makes a task seem boring is at least partly the opposite of what makes it interesting or intrinsically motivating. Simple, repetitive tasks that require little thought or judgment, such as some assembly line tasks, are likely to be experienced as boring. Once learned, these tasks require little conscious attention, provide little mental stimulation, and may prohibit incumbents from engaging in other forms of self-entertainment while working.

Another type of work that is often experienced as boring includes vigilance, inspection, checking, and driving tasks. These tasks require sustained and careful attention. However, they provide little variety or stimulation in return. This makes it difficult to sustain

attention and perform with high reliability over long periods of time.

A final category of work situation that is described as boring is having nothing to do. Some jobs do not contain enough tasks to keep incumbents occupied for the time they are required to remain at work. Other jobs are dependent on intermittent or less than completely predictable demand for services, such as checkout or help desk staff. When demand is low, there may be little to do but wait around in readiness to provide a service.

Work Environment

Compulsion and interruptions can also contribute to feelings of boredom while working, regardless of characteristics of the main work task. Individuals report feeling bored when they are compelled to perform tasks in set ways, in set places, and at set times. Lack of self-direction, autonomy, and personal causality are known to undermine intrinsic interest in work tasks.

Individuals may infer that they are bored when they experience problems holding their attention on a work task. Some research has suggested that low-level distractions and interruptions in the workplace can make maintaining attentional focus difficult, thus contributing to the experience of boredom. Interruptions can also stem from internal sources. Personal concerns may produce intrusive thoughts that distract an incumbent from a work task so it appears uninteresting.

Interactions of Task and Performer

Some authors attribute boredom largely to lack of personal meaning in an activity. Individuals are bored when they perform a task that lacks relevance for them. Simple repetitive tasks often fit this description, as might any required task when something else is more important or has greater meaning to the performer at that moment. Individuals are also bored when tasks are too difficult for their skills. Tasks may be varied and complex, but the performer lacks the expertise to extract meaning from the complexity. An example is listening to a lecture that is too advanced for a person's level of understanding.

REDUCING BOREDOM

Both individuals and organizations may act to reduce boredom. Bored employees adopt a number of

strategies to alleviate their unpleasant feelings. Sometimes it is possible to force attention on to the task and eventually become absorbed in it. Another option is to engage in *subsidiary behaviors* to provide additional stimulation while performing the boring task. For example, a worker may fidget, talk to others, daydream, listen to music, or invent varied ways to execute the task. If the task does not require full attention, these strategies may reduce boredom without compromising performance. Performance on vigilance tasks, however, will often suffer when subsidiary behaviors are performed. Alternatively, individuals may escape or avoid boring situations altogether by finding different work or nonwork tasks to do: engaging in counterproductive work behaviors such as horseplay or sabotage, taking breaks, being absent, or quitting the job.

Organizations may adopt job rotation or job enrichment and redesign to increase the variety and challenge in employees' tasks and thus reduce boredom. Frequent feedback, goal setting, and performance-contingent pay can make simple tasks more meaningful and therefore less boring. Although there is no research evidence yet, team-based work systems also might reduce boredom. Allowing social contact between workers and permitting other forms of concurrent self-entertainment can help reduce boredom on simple repetitive tasks. Because boredom occurs when skills are either too high or too low for task demands, creating an appropriate match between demands and skills through selection, training, and job design should minimize boredom.

C

CAREER DEVELOPMENT

Most people participate in some form of paid labor during their lifetime. Typically, they engage in a series of jobs. As these jobs become increasingly related to one another, a career unfolds. This process occurs throughout the life span. Several theories have been proposed to describe the process of career development. Three of the most frequently cited are *career development theory*, the *social learning theory of career decision making*, and the *social cognitive career theory*.

CAREER DEVELOPMENT THEORY

Donald Super first proposed his career development theory in 1953, making it one of the earliest theories on career development. Combining life-stage psychology and social role psychology, Super's theory addresses the significant roles and career development tasks that occur during life stages.

One element of Super's theory that combines life stages and social roles is the *life-career rainbow*, a graphic representation of *lifespace* and *life span*, key terms in Super's theory. Lifespace refers to the roles that a person assumes that are related to both work and nonwork; examples of lifespace roles include child or worker. The life-career rainbow depicts changes in the centrality of roles over time—for example, the development from daughter or son to full-time worker to retirement. Life span, or time, refers to stages in a career, which coincide with developmental stages such as childhood and adulthood. Super identified six

major stages of career development and the important developmental tasks of each stage. Additionally, Super estimated the age range during which most people go through each stage.

The first stage that Super proposed is *growth*, a period of childhood development that takes place from age 4 to 13. Major developmental tasks of this stage include developing a concern about the future, increasing personal control over one's life, motivating oneself to achieve, and acquiring competent habits and attitudes toward work.

The next stage of career development is *exploration*, occurring from age 14 to 24. Super asserted that during this stage, people crystallize, specify, and implement an occupational choice. During this stage individuals are constructing their self-identity by choosing and preparing for an occupation. Super concentrated much of his research on understanding development in this stage.

When individuals enter into a specific career, they begin the *establishment* stage. Establishment, which occurs between the ages of 25 and 45, is the process of stabilizing one's position in an organization. Furthermore, individuals consolidate their position by demonstrating positive work habits and attitudes. Many individuals focus on having families and developing skills to be a parent during this stage. Toward the end of this stage, individuals are expected to advance their work roles by taking on new responsibilities or working toward promotion.

Once an individual decides to continue in the same career, the *maintenance* stage begins. This stage comprises the remainder of the time spent in paid labor, typically lasting from ages 45 to 65. During this stage,

individuals continue to maintain the skills needed for the occupation they have chosen. They also continue to learn new skills to keep up with changes in their job.

The final career developmental stage is *disengagement*. Around age 65, when individuals plan for or begin the process of retirement, they enter the disengagement stage. At this time, individuals reduce their work efforts as they retire from their careers, and they shift the focus of their lifestyle from work to other activities such as family or leisure interests.

Though individuals are assumed to progress through the career stages at certain ages and in a particular order, Super concedes that the stages may not take place at the same age for everyone, and people may actually cycle through each stage more than once. This concept, known as *recycling*, suggests that individuals go through previous stages when they begin a new job or new career. Furthermore, the theory speculates that this cycle of developmental stages may also apply to non-work-related roles such as leisure activities or familial roles. For example, if an individual becomes physically unable to participate in athletic leisure activities, he or she may recycle back to the exploration stage to develop skills for a new leisure activity.

As people progress through the career development stages, the choices they make reflect their self-concept. In other words, as individuals select vocations, they attempt to choose a career that depicts their own self-image. Career development, then, is an iterative process whereby the congruence between self-concept and career increases with each subsequent occupation or job.

SOCIAL LEARNING THEORY OF CAREER DECISION MAKING

John Krumboltz's social learning theory of career decision making (SLTCDM) has its origins in Bandura's social learning theory of behavior. Krumboltz contended that individuals are guided into careers based on their learning experiences and skill knowledge. He also proposed that reinforcement, whether positive or negative, plays an important role in shaping self-efficacy and motivations for behaviors. For example, if a student does poorly in math, SLTCDM predicts that the student's interest and motivation in math courses will decline, and the student will not enter a career that requires math skills. On the other hand, if the same student is rewarded in music by winning a

competition, SLTCDM predicts an increase in that student's music self-efficacy, and he or she will be likely to pursue a career related to music. These are examples of instrumental learning experiences, in which preference is developed for activities in which one succeeds or is reinforced and interest is diminished if one fails, receives no rewards, or is punished for participating.

The learning process can also occur through observation or associative learning experiences. Instead of participating in activities, individuals can learn about specific occupations and careers vicariously from the media, role models, or peers. Positive or negative associations about an occupation then influence an individual's assessment of that occupation and affect whether he or she decides to pursue that occupation.

As individuals accumulate learning experiences, they begin to make judgments—called *self-observation generalizations*—about how well or how poorly they can perform specific tasks. These generalizations may be accurate or incorrect, but they influence how individuals try to translate their skills into possible occupations. These skills, which Krumboltz referred to as *task approach skills*, provide information about an individual's problem-solving ability, work habits, performance, and work values.

Career development in SLTCDM, then, is a continual process of learning that shapes one's self-observation generalizations and task approach skills. Like Super's idea of enacting one's self-concept, SLTCDM explains how accumulated learning experiences guide career decisions and how individuals identify occupations that match their interests and skills.

SOCIAL COGNITIVE CAREER THEORY

Social cognitive career theory (SCCT), proposed by Robert Lent, Steven Brown, and Gail Hackett, takes a cognitive approach to the process of career development. It was formulated in response to growing ideological changes that placed importance on people's cognitions. This theory posits that individuals' interests are first influenced by contextual factors such as education, support, and role models and by individual factors such as gender, race, and culture. Contextual factors and individual factors then influence one's self-efficacy in certain activities that, in turn, reflect one's interests. Therefore, SCCT places importance on the individual's cognitive process of choosing a career based on environmental and social factors,

self-efficacy, interests, and performance outcomes. Additionally, SCCT contends that as individuals gain more learning experiences over time, they revise their career-related self-efficacy.

Both SCCT and SLTCDM conceptualize career development as a continuous process of participating in activities, assessing one's success, and refining career choices based on self-evaluations. The difference between the theories is that SLTCDM emphasizes learning new activities, whereas SCCT emphasizes self-efficacy for the tasks in which an individual participates.

VARIATIONS IN CAREER DEVELOPMENT PATHWAYS

For many people, career development may not be orderly and predictable. For example, when women entered the workforce in the 1940s to replace the men who had been called to military service, many had never worked outside the home. However, women were—and still are—expected to care for their families in addition to working. The demands of working in both arenas have created somewhat different career paths for women and for men. The conflict between the roles of wife, mother, and worker often has an effect on women's career progression. For example, single working women are more likely to be promoted than women who are married and have children. For men, having children does not seem to have as much effect on career development.

Increasingly, both women and men are beginning to take more time away from their careers to spend time with their families; therefore, the tradition of participating in full-time paid labor for the majority of one's adulthood is changing. Workers are also beginning to decentralize the role of employment in their lives to pursue other interests. In response to this shift in priorities, employers have begun to adapt to parents' desire for more family time and flexibility by developing new work situations such as job sharing, working from home, or working part-time. Maternity and paternity leaves offer parents the opportunity to leave the workforce temporarily to raise children. As a result of these changes, career development may not be a linear process for parents who take time away from the workforce to raise families.

Another group that has experienced variations in career development is immigrants. During the 20th century, the rapid increase in technology and

globalization of corporations made the world smaller. One result was the migration of workers. For immigrants in a new country, especially professionals, entering a career is more challenging than it is for citizens of that country. For example, people who are trained as doctors or lawyers in other countries may find they are unable to work in the United States because their training is not transferable. Therefore, they must retrain in the same career or move into another profession. Other challenges to career development for immigrants may include language barriers, access to well-paying jobs, difficulty obtaining a work visa, or discrimination.

APPLYING CAREER DEVELOPMENT THEORIES

Though career development theories offer some valuable explanations of the process of career choice and development, these theories do not address career decisions and career commitment that may result from external factors such as family expectations, job availability, or even occupational prestige. Moreover, for people who do not have the luxury of choosing occupations based on their interests or self-efficacy—for example, women, parents, or immigrants—extant developmental theories may not provide an adequate model of the process of career development. On the other hand, career development theories do offer some direction for career counselors. For example, Super suggested a counseling approach to apply his theory to practice. That approach includes assessments to help clients gain information about their level of career development, as well as information about their interests and values to identify potential careers. Krumboltz also provided suggestions for applying his theory, SLTCDM, to practice. Consistent with that theory's emphasis on learning, he suggested that counselors help clients recognize salient career information they have learned in past jobs and reframe unexpected incidents into positive career opportunities. Finally, SCCT provides a framework for counselors to address clients' career issues. At its core, career counseling modeled on SCCT assesses clients' self-efficacy for various activities and uses this information to suggest possible careers. Furthermore, counselors address perceived barriers to careers to give clients more options to pursue.

CAREERS

A career differs from a job in terms of the length, breadth, and depth of personal involvement. A career is a profession in which one makes progressive achievement, whereas a job is defined by specific tasks. Establishing a career serves many purposes, including providing sustainable income, expressing personal beliefs and values, and providing social connections.

CAREER PATHS

Most individuals move through three career stages, each of which is associated with different social and psychological characteristics. During the first stage, individuals are motivated to establish a foundation in the organization and seek opportunities for advancement. The second stage, midcareer, is a time for people to seek new meanings and reenergize. For others, midcareer coincides with midlife crises or problems related to health and family, and it presents challenges related to work. For example, an individual may reach a career plateau when he or she progresses to a point at which hierarchical promotions are unlikely. The third stage, or late career, is a time when individuals maintain their established career status and gradually disengage from the full-time workforce. During this stage, many individuals seek part-time work, increase their volunteer activities, and become

valuable resources for the community in alternative ways.

HISTORY OF CAREER

The modern concept of the career can be traced to the Industrial Revolution. Before the 1800s, individuals worked primarily on family-owned farms. The Industrial Revolution introduced factories and modern industries, and many individuals moved to cities to work. During World War I, the first systematic placement of individuals in jobs took place. Using group-administered tests developed for the military, individuals' potential and expertise could be matched quickly with job demands.

The Great Depression of the 1930s raised the unemployment rate from 3.2% in 1929 to 23.6% in 1932; during this time, people worked more for survival than for personal fulfillment. World War II introduced 6 million workers into the workforce, the majority of whom were married women. After the war, counseling centers designed to serve returning veterans were established to address their career rehabilitation concerns. Over time, sophisticated tests and counseling tools were developed to help people make decisions related to career choice and development. More recently, the workforce has become increasingly diversified, raising important issues about career choice and work adjustment for workers of color and workers with different sexual orientations, disabilities, and lower social economic status.

CAREER SATISFACTION AND WELL-BEING

One important issue that is related to career is the contribution that work makes to individual well-being. Whereas unemployment rates are linked to mental and physical problems, maintaining a career helps individuals to stay active and connected. Research has shown, for example, that individuals with mental and physical disabilities who are able to enter the workforce, do part-time work, or even do volunteer work experience fewer symptoms, report higher self-esteem, and enjoy a better quality of life compared with nonworking peer groups.

Recently, occupational stress has been identified as a major cost for business organizations. The field of *occupational health psychology* is a new discipline that is dedicated to identifying individual and organizational factors that contribute to occupational

stress and career dissatisfaction. For example, research has shown that organizational variables such as environmental uncertainty, role conflict, opportunities for skill acquisition, social contact, physical security, organizational structure and climate, and physical, emotional, and cognitive job demands have both a direct and an indirect impact on individuals' sense of career satisfaction and level of occupational stress.

WORK-FAMILY BALANCE AND CAREERS

Although a broad distinction can be made between work life and nonwork life, the boundaries between work and home have become increasingly blurred. Two reasons for this trend are that married women have entered the workforce and communication technology has advanced. Dual-earning couples today face the challenge of balancing their work and home lives. Cell phones, the Internet, and portable computers allow individuals to work when they are at home or on vacation. Thus, technological advances have made it difficult for individuals to maintain boundaries between work and home.

Two perspectives, *scarcity* and *expansion enhancement*, attempt to explain the interactions between work and family. The scarcity perspective assumes that multiple roles at work and at home compete for an individual's psychological and physiological resources. Generally, work-to-family conflict is linked to outcomes such as marital dissatisfaction and family distress. Family-to-work conflict is associated with poor work performance, low job satisfaction, and work-related absenteeism. In contrast, the expansion-enhancement perspective emphasizes the benefits of multiple roles in life, which may outweigh the cost of additional stress.

CAREER THEORIES

Some of the most influential career theories include John Holland's person-environment typology; René Dawis and Lloyd Lofquist's theory of work adjustment; Donald Super's developmental approach; and Robert Lent, Steven Brown, and Gail Hackett's social cognitive career theory. Holland's theory proposes six types of vocational interest personality—realistic, investigative, artistic, social, enterprising, and conventional—and describes the way those interests fit work environments. The theory of work adjustment

captures the dynamic interaction between individual workers' needs and abilities and the reinforcers and skill requirements of jobs. Super's model outlines six stages of career development that occur throughout the life span. Social cognitive career theory identifies the personal, environmental, and behavioral variables that influence career choices. The theory also focuses on the connection between self-efficacy, interests, outcome expectancy, environmental supports, and social barriers that people experience when making their career choices.

CAREER ASSESSMENT AND COUNSELING

The field of career counseling has continued to evolve since it was established during the early 1900s. Today, career counselors work in a variety of settings: schools, hospitals, business organizations, public services, and private practice. They help individuals explore career options, plan for career paths, locate job placements, and better understand how social and personal concerns interact with one's career. Career counselors use assessment instruments to help individuals explore factors that may influence their career choices. Four frequently assessed constructs are interests, personality, needs and values, and abilities. Major interest inventories used in career counseling include the Strong Interest Inventory, the Campbell Interest and Skill Survey, and the Self-Directed Search. The Myers-Briggs Type Indicator and the California Psychological Inventory are two popular personality measures. Value measures include instruments such as the Minnesota Importance Questionnaire and the Values Scale. Both self-report and objective assessment instruments of abilities are available. For example, the Harrington-O'Shea Career Decision-Making System has a section devoted to self-estimated abilities. The most often used objective assessment instruments are the Differential Aptitude Tests, the Armed Services Vocational Aptitude Battery, and the General Aptitude Test Battery.

3. Collective case: Multiple cases (either individuals or organizations) are used to explore an issue. One application of this method could be an examination of selection practices for assembly line workers in four different automotive organizations.
4. Collective instrumental case: Multiple cases provide evidence in support of a point. For example, organizations that recently implemented a 360-degree feedback system could be selected to support the argument that these systems are most appropriate for developmental purposes.

CASE STUDY METHOD

A *case study* is an in-depth examination of entities (individuals or organizations), processes, or activities that seeks further theoretical understanding and practical knowledge of some phenomenon. This qualitative research tool relies on a variety of techniques to achieve context-rich, detailed information about a single group or issue. Historically, case studies reflect the postmodern view of research, which emphasizes inductive and subjective methods rather than deductive and objective approaches to assessing behavior within context. Case studies have been used extensively in the political science, sociology, and education literature.

Because of the inherent flexibility of this method of study, case studies can be used to move beyond the extant empirical or theoretical literature to investigate creative and innovative solutions to organizationally relevant problems. There are many types of case studies, each reflecting a different method of addressing the research question under investigation. Delbert Miller and Neil Salkind identified four general types of cases:

1. Intrinsic case: The case (individuals or organizations) itself is of interest. An examination of best practices for Web-based training within a single technologically advanced organization is an example of an intrinsic case study.
2. Instrumental/illustrative case: The research question involves the examination and description of a specific issue in the context of a single unit of study; the case is used as a means to explore this question. For example, the abuse of skill-based pay plans could be researched in an organization that recently implemented this pay system to illustrate how important guidelines are to appropriate expenditures.

DATA COLLECTION AND ANALYSIS

The design and incorporation of hypotheses depends on the nature of the research. Like traditional quantitative research, theory and expectations should guide the design of qualitative research when possible. The identification and number of participants should reflect this theory and boundaries. However, in some instances, case studies are used as the primary tool for theory building, making it difficult for the researcher to identify expectations or propositions prior to designing the study. In other instances, the case study may be used to verify existing theory with one or more organizations in context; in this situation, expectations or hypotheses should be explicated prior to designing the study.

Yin identified a number of techniques that can be used to conduct case study research. These include participant observation, direct observation, interviews, document analysis, archival data analysis, and field studies. Thorough explication of the methodology and participants involved in the case study is critical to enhancing perceptions of the generalizability and meaningfulness of the findings. Additionally, the use of multiple standardized methods to triangulate across sources can bolster the representativeness of case study results.

Once the data are collected, analysis traditionally progresses in one of two ways: holistically or through the use of coding schemes. This analysis may occur within a single case, across individuals, or across multiple cases. If the researcher is interested in the information obtained as a whole rather than smaller units of meaning, the holistic method of analysis is used. In this instance, general patterns or themes of behavior are identified in the data. Alternatively, elements of the material gathered can be coded to quantify the prevalence of certain themes or behaviors across

individuals or organizations. Because of the subjective nature of the coding process, the use of multiple coders and some assessment of intercoder reliability (e.g., Cohen's kappa) is strongly recommended.

STRENGTHS OF THE CASE STUDY METHOD

The main benefit of case study research is the depth of information provided about a single unit (person, organization, or issue) within context. This detailed information, often referred to as *thick descriptions*, provides a real-world context in which the processes under investigation can be better understood. Because it focuses on the context of events and behaviors, this type of research may be more relevant to the practitioner than mean-level, quantitative survey data.

Case study research may also benefit theory building and result in more robust theories that reflect contextual influences. Because of the inherent flexibility of the techniques associated with the case study method, researchers can better identify unexpected themes or results and further explore these to build more realistic theories. Some qualitative researchers argue that the case study method has high construct validity because it does not place constraints on the situation, traditionally a necessary element of quantitative research.

WEAKNESSES OF THE CASE STUDY METHOD

The most common argument against the use of the case study method as a technique for scientific inquiry is the lack of generalizability of findings because of the narrow focus and sample. For many researchers, external validity only involves the use of sample data to approximate population parameters in order to identify a universal law of behavior and achieve statistical generalizability. Proponents of the case study method argue that researchers should focus instead on analytical generalization, whereby findings are generalized to a broader theory. Additionally, researchers using multiple groups of individuals or multiple organizations to triangulate across sources can argue for increased generalizability of patterns or themes.

Internal validity may also be an issue in case study research in that there is little to no control over the factors influencing the behavior or individuals of interest. This lack of control may call into question the establishment of any patterns of behavior. However,

the creation and evaluation of alternative explanations for repeated patterns of behavior can help the case study researcher to refute claims of a lack of internal validity of results.

Because of the inherent subjectivity of the case study process, which is a result of the individualistic techniques used (e.g., interviews, observation), the reliability of results is often questioned. Case study researchers argue, however, that the consistency of the case study process can be enhanced by thorough research protocols with careful documentation. Some have argued that researchers should shift their thinking to an examination of dependability, or the stability and consistency of the *process* of collecting the in-depth data, rather than focusing on the *outcome* of the data-collection procedure.

SUMMARY

The case study method of research provides context-rich information about an individual or group, process, or activity. As a qualitative and subjective method of inquiry, it suffers from problems with internal and external validity, as well as reliability in results. However, its disadvantages are balanced by the rich detail it provides, which contributes to theory development and practical understanding of issues that are relevant to social scientists and those interested in organizational behavior. The use of multiple sources and multiple methods can enhance perceptions of the utility of this method of research.

CHARISMATIC LEADERSHIP THEORY

Charismatic leadership is a relatively new and distinct paradigm. Since the 1970s, researchers have conducted studies on charismatic leadership in areas such as management, academia, the military, and government. Although researchers have used different approaches to study charismatic leadership, their findings have been fairly consistent.

Through empirical investigation, researchers have uncovered the key features of charismatic leadership. Charismatic leadership theory identifies the extraordinary characteristics that inspire devotion and motivation in followers and highlights the relationship between charismatic leaders and their followers. Studies describe charismatic leaders as highly influential and confident individuals who hold strong beliefs. They are change agents who communicate their vision to others, set high expectations, attend to the needs of their followers, and behave in unconventional ways. Researchers assert that charismatic leadership tends to manifest itself in crisis situations, when the leader is of high authority, when vague and complicated assignments are given, and when extrinsic rewards are not offered. These circumstances provide opportunities for charismatic leaders to implement change and to promote their vision.

Charismatic leaders are inherently motivated and committed to setting and meeting their goals. They are naturally diplomatic and work in partnership with their followers to identify organizational issues and undertake challenges and risks. They maintain a collective identity while providing a sense of direction that helps followers achieve both organizational and personal goals.

RESEARCH ON CHARISMATIC LEADERSHIP

Researchers have documented the positive effects of charismatic leadership. For example, they have found that followers of charismatic leaders not only support and trust their leader but also strive to accomplish their manager's mission. They often learn from their leader and emulate his or her behavior. Studies suggest that followers embrace a charismatic leader and his or her mission because of the leader's self-confidence, exceptional persona, extraordinary vision,

ideology, and motivation to maximize his or her subordinates' potential. Typically, followers experience higher satisfaction than do counterparts without charismatic leaders. However, findings from previous studies show that charismatic leaders can also create divisions within the groups they lead, display an authoritative management style, and focus on trivial matters.

LIMITATIONS OF CHARISMATIC LEADERSHIP THEORY

Despite the amount of research that has been conducted on charismatic leadership theory, the exact definition of charismatic leadership remains uncertain. Some researchers assert that leaders are considered charismatic when followers perceive their leader as possessing extraordinary characteristics and when followers develop strong ties with their leader; however, such attributes are based on several presumptions: the quantity of components demonstrated in a leader's behavior, the significance of the components, and the amount of influence of the components. Some of these components include the leader's focus on the organizational environment, future goals, and likeability. Some researchers affirm that charismatic leadership exists when a leader affects a follower's attitude and drive, even if the follower does not characterize the leader as exceptional or charismatic. Alternatively, others argue that a leader's traits, followers, and situation collectively determine whether charismatic qualities are present.

Researchers suggest that charismatic leadership is not essential or necessary. Some argue that an organization's vision is created through the collaborative efforts of leaders and subordinates, and some insist that major transformations within organizations occur as a result of transformational leaders. Still others argue that charismatic leadership is needed during turbulent or stressful times—for example, when a company experiences a reduction in its workforce or when an organizational merger occurs.

Charismatic leadership theory fails to provide a well-defined explanation of the significance of underlying influence processes. Some theorists propose that personal identification is the primary influence process, whereas others contend that collective identification and internalization are the dominant influence processes. They claim that followers become loyal to

their leader and eagerly execute the leader's tasks and objectives. These devoted followers work diligently to gain their charismatic leader's approval and tend to emulate their leader's behavior.

On the other hand, others contend that collective identification and internalization are the dominant influence processes. They claim that if internalization is the dominant influence process and followers are goal oriented, the attainment of goals will be an integral part of their self-confidence. Consequently, followers will work assiduously to fulfill their goals and exhibit more loyalty to their tasks than to the charismatic leader. Followers will likely refrain from executing the leader's unrealistic goals and presumably reject objectives that infringe on their principles.

Unfortunately, there is not a shared understanding of the fundamental behaviors of charismatic leadership. Although the majority of studies on charismatic leadership address leader behaviors, there is presently no agreement among theorists regarding the essential behaviors of charismatic leadership, nor is there a clear understanding of the relationship between leader behavior and the rationale behind that behavior. Most of the behaviors seem to have been identified by their association with socialized leadership effectiveness rather than their link to qualities of charisma.

Additionally, there seems to be a greater focus on socially accepted behaviors than on manipulative behaviors. Some charismatic leaders engage in manipulative behaviors by inflating situations so as to depict a crisis, reprimanding others for their mishaps, and overstating their accomplishments. These manipulative behaviors often create dependent followers and a propensity for leaders to be viewed as experts.

CIVIL RIGHTS ACT OF 1964, CIVIL RIGHTS ACT OF 1991

The Civil Rights Act of 1964 (CRA 1964) is a landmark piece of legislation that created the legal basis for nondiscrimination in housing, education, public accommodations, federally assisted programs, and employment. Title VII of the CRA 1964 prohibits discrimination in employment based on an individual's race, color, religion, sex, or ethnic origin. This prohibition applies to a wide range of employment actions, including hiring, promotion, training, compensation, disciplinary actions, discharging of employees, and other actions pertaining to the "terms, conditions, or privileges of employment" as set forth in the act. Title VII also makes it unlawful for an employer to take retaliatory action against any individual for opposing employment practices made unlawful by Title VII; filing a discrimination charge; or testifying, assisting, or participating in an investigation, proceeding, or hearing under Title VII. The act generally applies to all employers with 15 or more employees; the U.S. government, however, is the most notable exception (federal employees are protected from discrimination by other legislation).

Title VII is the single most influential fair employment law in the United States. It is credited with improving the availability of meaningful employment opportunities for women and minorities and reducing the wage disparities these groups historically experienced. With the passage of Title VII, employers could no longer make biased employment decisions with impunity. The legal obligations imposed on employers by Title VII—and the greatly increased threat of employment litigation—prompted employers to reconsider their employment practices and, in many instances, make changes that were improvements from a behavioral science perspective (e.g., greater efforts to use criteria with demonstrable job-relatedness).

Since its enactment, Title VII has been amended several times. The most far-reaching amendments were made by the Civil Rights Act of 1991 (CRA 1991). The following sections discuss Title VII and its

interpretation by the courts, both before and after the 1991 amendments.

CIVIL RIGHTS ACT OF 1991

The CRA 1991 was enacted in response to a series of U.S. Supreme Court decisions that were widely viewed as adversely affecting victims of employment discrimination. In addition to making far-reaching amendments to Title VII, the CRA 1991 also amended aspects of the Americans With Disabilities Act of 1990 (ADA), the Age Discrimination in Employment Act of 1967 (ADEA), and the Civil Rights Act of 1866 (CRA 1866).

Extended Coverage of Fair Employment Laws

The CRA 1991 broadened the coverage of U.S. fair employment laws in two ways. First, it extended the application of Title VII and the ADA to U.S. citizens working abroad for U.S.-based employers. This provision reversed the Supreme Court's 1991 decision in *EEOC v. Arabian American Oil Co.*, which held that Title VII does not apply outside the United States. Second, the CRA 1991 extended the application of all major federal fair employment laws (e.g., Title VII, the ADA, and the ADEA) to previously unprotected Senate employees, allowing them to redress employment discrimination claims through an internal procedure and a limited right of appeal in federal court (employees in the House of Representatives were already covered).

Required Proof in Employment Discrimination Cases

Title VII, the ADA, and the ADEA all recognize two basic theories of discrimination: disparate treatment and disparate impact. The CRA 1991 includes several provisions that either reversed or codified Supreme Court decisions regarding procedural and evidentiary requirements in these two distinct types of cases.

Disparate Impact Cases

Disparate impact discrimination claims involve employer policies or practices that appear neutral on their face but have a substantially greater negative impact on a group that is protected by fair employment

legislation (e.g., gender, race, age, disability) when put into effect. For example, although an employer's use of height requirements in its hiring decisions appears to be race neutral on its face, the requirement was found to have a substantially greater impact in screening out Hispanic and Asian job applicants because those two groups tend to be shorter than White applicants.

The Supreme Court's 1989 decision in *Wards Cove Packing Co. v. Atonio* made it significantly more difficult for plaintiffs to prove disparate impact by holding that it is not enough for a plaintiff to show there is a racial, ethnic, or gender imbalance in the employer's workforce; rather, the plaintiff must identify the specific policy or requirement that produced the disparate impact. For example, a plaintiff could not merely show that significantly fewer women hold entry-level jobs compared to the proportion of females in the relevant labor market; instead, the plaintiff would have to identify the specific recruiting or selection practice that has differentially kept women from being hired.

The CRA 1991 made the plaintiff's burden in disparate impact cases somewhat easier to meet by providing that if the plaintiff can demonstrate that the elements of an employer's decision-making process are not capable of separation for analysis, it is not necessary for the plaintiff to identify the specific policy or practice causing the disparate impact. For example, if it is not possible to determine the criteria used to screen applicants or select employees because of a highly subjective hiring process, the plaintiff may make a prima facie case of disparate impact discrimination without identifying the specific policy or practice.

Even if a plaintiff is able to establish that an employer's practice has had a disparate impact on a protected group, a finding of illegal discrimination does not automatically follow. Instead, the employer is permitted to attempt to justify the use of the challenged practice. In addition to making it harder to prove disparate impact by requiring plaintiffs to identify the specific practice causing it, the *Wards Cove* decision also made it easier for employers to avoid liability because all an employer needed to do to justify such a practice was to produce some proof the challenged practice was "reasonable."

In response to the *Wards Cove* ruling, the CRA 1991 made it more difficult for employers to establish a legal defense for a practice found to have a disparate impact. First, the act increased the employer's burden by requiring that once a plaintiff establishes the fact of disparate impact, the employer must demonstrate that

the challenged practice is both job related and necessary for business. Although the CRA 1991 does not define these terms, it is well settled that it is not enough for the employer to show that it acted in good faith, that it had some nondiscriminatory reason for the practice, or that the practice was merely reasonable. Instead, the employer must produce credible evidence showing that the requirement is related to performance on the job. For example, although formal validation studies are not necessarily required, if it is shown that an employer's use of a selection test has a disparate impact on the hiring of minorities, evidence of significant correlation between applicant scores on the selection test and performance on the job would allow the employer to establish a defense.

The CRA 1991 also made it more difficult for employers to establish a defense to a showing of disparate impact by making it clear that the employer not only has to *produce* some evidence indicating the challenged practice is job related and consistent with a business necessity, the employer must also *persuade* the court of that alleged fact. As a practical matter, this means that if the plaintiff produces contradictory evidence of equal quality, the employer would fail to establish a legal defense (i.e., "ties" go to the plaintiff).

Mixed-Motive Disparate Treatment Cases

Disparate treatment discrimination claims involve intentional discrimination in that the employer is alleged to have intentionally used race, gender, or another protected characteristic as a factor in an employment decision or action. In a "mixed-motive" disparate treatment case, there is evidence that the protected characteristic in question was only one of multiple factors influencing the employer's decision; in other words, a discriminatory motive was a factor, but not the *only* factor contributing to the employment action in question.

The 1989 Supreme Court decision in *Waterhouse v. Hopkins* made it more difficult for plaintiffs to meet their burden of proving disparate treatment in mixed-motive cases by holding that the plaintiff loses in such cases if the employer can show the same decision would have been made even without the unlawful motive (for example, because the plaintiff was objectively less qualified). The CRA 1991 clarified that intentional discrimination occurs when race, color, sex, religion, or national origin is a motivating factor

in an employment decision, even if there are other nondiscriminatory reasons for the decision. Although an employer's proof that it would have made the same decision in any event is no longer a complete defense in mixed-motive cases, such a showing is a partial defense in that, if established, the damages available to the plaintiff are limited.

Damages Available to the Successful Plaintiff

Prior to the passage of the CRA 1991, remedies for discrimination under Title VII and the ADA were limited to "make-whole" relief (e.g., back pay, lost future earnings, attorneys' fees, court costs) and injunctive relief. The CRA 1991 added compensatory damages and punitive damages in certain circumstances. Compensatory damages (e.g., emotional distress, mental anguish, loss of enjoyment of life) may be recovered by victims of disparate treatment or intentional discrimination under Title VII and the ADA. Punitive damages may be recovered if the employer is shown to have acted with malice or reckless indifference for the law. However, the total amount of compensatory and punitive damages available for victims of intentional discrimination is capped at \$50,000 to \$300,000, depending on the size of the employer.

The damages available to plaintiffs in Title VII and ADA cases may be further limited in mixed-motive intentional discrimination cases if the employer is able to establish the "same-decision" defense. That is, even if it is established that an employer had a discriminatory motive (e.g., gender was a motivating factor in the decision), if the employer can show that the discriminatory intent did not have any practical effect because the employer would have reached the same decision even without the discriminatory intent, then the plaintiff is not entitled to reinstatement, back pay, or compensatory or punitive damages. However, the plaintiff may receive declaratory and injunctive relief, as well as attorneys' fees and costs.

Right to a Jury Trial

When Title VII was passed in 1964, there was concern that some Southern juries would not be able to render a fair verdict in discrimination cases. As a result, jury trials were not permitted under Title VII as it was originally enacted—the judge assigned to the case decided both questions of law and issues of fact

(e.g., did the employer intentionally discriminate?). Under Title II, the CRA 1991 permits jury trials at the request of either the plaintiff or the defendant when compensatory or punitive damages are sought. Because compensatory and punitive damages are unavailable in disparate impact cases, jury trials are not available either.

OTHER PROVISIONS

The CRA 1991 also includes the following provisions:

- Banning *race norming*, the practice of adjusting scores, using different cutoff scores, or otherwise altering the results of employment-related tests based on race, color, religion, sex, or national origin to ensure that an employer has a minimum number of minority applicants
- Establishing the Glass Ceiling Commission to study the opportunities for and artificial barriers to the advancement of women and minorities to management and decision-making positions in business
- Broadening protection against private race discrimination based on Section 1981 of the CRA 1866
- Expanding the right to bring claims challenging discriminatory seniority systems
- Limiting the rights of nonparties to attack consent decrees in employment discrimination cases by barring any challenges by parties who knew or should have known of the decree or who were adequately represented by the original parties

IMPACT OF THE CRA 1991

The CRA 1991 significantly expanded the legal rights and remedies available to victims of discrimination in the American workplace. The objective increase in the likelihood that a plaintiff could succeed at trial, as well as the substantial increase in monetary damages potentially available to plaintiffs, prompted employers to become more concerned with the threat of employment discrimination litigation. Empirical evidence indicates that the perceived greater threat of employment litigation was, in fact, realized. For example, research examining employment lawsuits filed before and after the passage of the CRA 1991 indicates the number of federal cases alleging discrimination in employment more than doubled from 1991 to 1995; the greatest increase came from lawsuits by former employees alleging discrimination in a firing decision (a trend that had begun before the passage of the CRA

1991). The amount of monetary awards received by plaintiff workers in employment discrimination cases also increased dramatically over the same period, although there is evidence that media reporting contributed to a greatly inflated perception of these awards.

The effect of the CRA 1991 on employment levels for women and minorities was less dramatic. Critics of the CRA 1991 argued that the threat of hiring-based disparate impact lawsuits would force employers to hire by quota. That is, employers would simply hire representative percentages of applicants from protected groups—with little or no regard for applicants' actual job qualifications—to avoid statistical disparities that might lead to a disparate impact claim. However, others argued that the cost of discharge litigation would motivate employers to avoid hiring minorities and women because of the perceived greater risk associated with firing employees in those groups. Overall, studies looking at the impact of the CRA 1991 on the employment of women and minorities suggest that quota-based hiring fears were unfounded. However, unlike Title VII, the CRA 1991 does not appear to have significantly improved the employment level of women and minorities in industries with traditionally low representations of those groups, nor does it appear to have led to significant gains in wages. In fact, a recent study suggests that employers with greater susceptibility to employment discrimination litigation actually reduced their hiring of protected workers after the passage of the CRA 1991.

Finally, as a result of the increased threat of litigation following the passage of the CRA 1991 and the act's emphasis on the need for employers to provide credible evidence of the job-relatedness of their employment practices, the role of industrial and organizational psychologists and well-trained human resource professionals within an organization has taken on greater importance. As others have argued, it appears that the best approach to dealing with the increased litigation threat posed by the CRA 1991 is to use the type of sound employment practices developed and promoted by these groups of professionals.

CLASSICAL TEST THEORY

Measurement is the process of quantifying the characteristics of a person or object. Theories of measurement help to explain measurement results (i.e., scores), thereby providing a rationale for how they are interpreted and treated mathematically and statistically. Classical test theory (CTT) is a measurement theory used primarily in psychology, education, and related fields. It was introduced at the beginning of the 20th century and has evolved since then. The majority of tests in psychology and education have been developed based on CTT. This theory is also referred to as *true score theory*, *classical reliability theory*, or *classical measurement theory*.

Classical test theory is based on a set of assumptions regarding the properties of test scores. Although different models of CTT are based on slightly different sets of assumptions, all models share a fundamental premise postulating that the observed score of a person on a test is the sum of two unobservable components, *true score* and *measurement error*. True score is generally defined as the expected value of a person's observed score if the person were tested an infinite number of times on an infinite number of equivalent tests. Therefore, the true score reflects the stable characteristic of the object of measurement (i.e., the person). Measurement error is defined as a random "noise" that causes the observed score to deviate from the true score.

ASSUMPTIONS OF CTT

Classical test theory assumes linearity—that is, the regression of the observed score on the true score is linear. This linearity assumption underlies the practice

of creating tests from the linear combination of items or subtests. In addition, the following assumptions are often made by classical test theory:

- The expected value of measurement error within a person is zero.
- The expected value of measurement error across persons in the population is zero.
- True score is uncorrelated with measurement error in the population of persons.
- The variance of observed scores across persons is equal to the sum of the variances of true score and measurement error.
- Measurement errors of different tests are not correlated.

The first four assumptions can be readily derived from the definitions of true score and measurement error. Thus, they are commonly shared by all the models of CTT. The fifth assumption is also suggested by most of the models because it is needed to estimate reliability. All of these assumptions are generally considered "weak assumptions," that is, assumptions that are likely to hold true in most data. Some models of CTT make further stronger assumptions that, although they are not needed for deriving most formulas central to the theory, provide estimation convenience:

- Measurement error is normally distributed within a person and across persons in the population.
- Distributions of measurement error have the same variance across all levels of true score.

IMPORTANT CONCEPTS IN CTT**Reliability and Parallel Tests**

True score and measurement error, by definition, are unobservable. However, researchers often need to know how well observed test scores reflect the true scores of interest. In CTT, this is achieved by estimating the *reliability* of the test, defined as the ratio of true score variance to observed score variance. Alternatively, reliability is sometimes defined as the square of the correlation between the true score and the observed score. Although they are expressed differently, these two definitions are equivalent and can be derived from assumptions underlying CTT.

To estimate reliability, CTT relies on the concept of *parallel test forms*. Two tests are considered parallel if they have the same observed variance in the population of persons and any person has the same true score

on both tests. If these conditions hold, it can be shown that the correlation between two parallel tests provides an estimate of the reliability of the tests.

Validity Versus Reliability

The definition of true score implies an important notion in CTT: that the true score of a person on a measure is not necessarily the same as that person's value on the construct of interest. *Validity* concerns how well observed scores on a test reflect a person's true standing on the construct that the test is meant to measure. As such, validity is a concept that is totally distinct from reliability. Reliability reflects the strength of the link between the observed score and the true score, whereas validity indexes the link between the observed score and the construct of interest. The reliability of a test sets an upper bound for its validity; hence, a test cannot have high validity with low reliability.

BEYOND CTT

As useful as it is, CTT has certain limitations. It has been criticized for its nonspecific concept of measurement error. Its assumption about the linearity of the regression line of observed score on true score has also been questioned on both theoretical and empirical grounds. Accordingly, more sophisticated theories have been proposed to address those limitations. In particular, generalizability theory explicitly considers the contributions of multiple sources of measurement error to observed scores and offers methods for estimating those effects. Item response theory postulates a nonlinear regression of a person's responses to a test item on his or her latent ability (a concept that is similar to true score in CTT). These measurement theories offer certain advantages over CTT, but they are more complex and depend on stronger assumptions. Therefore, CTT remains popular because of its simplicity and, more important, the robustness against violations of its basic assumptions.

—Huy Le

CLASSIFICATION

See PLACEMENT AND CLASSIFICATION

COGNITIVE ABILITIES

The term *cognitive ability* generally refers to the capacity to mentally process, comprehend, and manipulate information—in short, the ability to learn. For example, reasoning deductively or inductively, grasping general principles from observing the behavior of objects, mentally rotating objects in one's mind, quickly and accurately comprehending what one is reading, and dealing effectively with mathematical concepts are all cognitive abilities. Cognitive abilities largely constitute what most people intuitively call *intelligence*. Cognitive abilities are also referred to as *cognitive aptitudes*.

The scientific study of cognitive abilities has a long and sometimes contentious history. However, researchers' interest has centered on two common themes: the structure of cognitive abilities (i.e., how many are there, and what do they look like?) and the impact of differences in cognitive abilities on outcomes of importance (i.e., what do they predict?).

THE STRUCTURE OF COGNITIVE ABILITIES

The debate over the structure of cognitive abilities is perhaps one of the most storied arguments in differential psychology. At the risk of oversimplifying its history, the debate largely centers on the question of whether there is a single general cognitive ability or many independent specific abilities. Today, most scientists accept a model of cognitive abilities similar to the one proposed by John B. Carroll. In an exhaustive and remarkable endeavor, Carroll reanalyzed more than 400 data sets spanning more than 60 years of research. His results convincingly demonstrated that the psychometric structure of cognitive abilities is

best described by a hierarchical model with three basic strata or levels. At the apex is a single general cognitive ability factor, referred to as *g*, below which are a small number of narrow abilities, often referred to as group factors, each of which sits, in turn, on top of a large number of task-specific abilities. The primary levels of interest are the top level (*g*) and the second level, which contains 8 to 10 narrow abilities.

Definition of the *g* Factor

The *g* factor reflects one's general ability to learn. Formally, it is defined as the "education of relations and correlates," that is, the ability to infer or deduce meaningful principles and concepts from abstract and novel situations. The *g* factor is reflected in the pervasive positive correlations among any set of tests or tasks that require any form of cognitive manipulation or processing of information. That is, although more narrow mental abilities (e.g., verbal ability, quantitative ability, visual-spatial ability, short-term memory) can be identified, people who are high (or low) on any individual narrow ability tend to be relatively high (or low) on the others. Reliable measures of cognitive abilities are always positively correlated.

Definition of Narrow Abilities

There remains some slight disagreement and uncertainty regarding the exact specification of narrow abilities. In fact, Carroll himself cautioned that some slight modification or further refinement to those factors may be in order. Nonetheless, the following narrow abilities are included in most models of cognitive abilities:

- Fluid intelligence/reasoning: The ability to apply rules and premises to reach a solution; the ability to discover the underlying characteristics that govern problems
- Quantitative reasoning/skills: The ability to reason, either inductively or deductively, with mathematical concepts, relations, and properties; general knowledge of mathematical concepts
- Crystallized intelligence: The size and sophistication of one's vocabulary; the ability to comprehend and communicate orally and use communication skills with fluency; the range of general and acculturated knowledge
- General verbal ability: The ability to recognize and decode words or disguised words; the ability to

comprehend and communicate with clarity of thought and expression in written discourse; general understanding of language rules of (native) language

- Short-term memory: The ability to form and store mental representations of stimuli and then recognize or recall them after a short duration (memory span, visual memory)
- Long-term associative storage and retrieval: The ability to store and recall previously learned material regardless of whether it is meaningful; the ability to rapidly produce series of ideas, words, or other elaborative information related to a specific theme or object; the ability to rapidly produce novel or uncommon connections among stimuli or solutions to problems
- Visual-spatial processing: The ability to mentally manipulate objects or visual patterns, such as mentally rotating multidimensional objects in space; the ability to quickly discern a meaningful object from partially obscured or vague patterns and stimuli
- Auditory processing: The ability to process speech sounds; phonological awareness; the ability to discriminate speech sounds in normal and distorted contexts; the ability to discriminate tones, tone patterns, pitch, and other variations in sound qualities; the ability to localize sounds in space
- Cognitive processing speed: The ability to rapidly make simple decisions or perform simple tasks; the ability to compare visual symbols; the ability to rapidly manipulate and deal with numbers in elementary ways

PREDICTIVE VALIDITY OF COGNITIVE ABILITIES

That differences in cognitive abilities exist and that they appear to have something to do with differences in a wide array of behaviors has been recognized for several thousand years. Therefore, a wide variety of methods for assessing individual differences in cognitive abilities have been developed, and many have proved useful in understanding or predicting behaviors as varied as academic performance and technical job performance, occupational and economic attainment, delinquency, criminal behavior, accident proneness, and mortality, to name just a few.

Predictive Validity of *g*

A wealth of data has confirmed that *g* is predictive (at levels of both theoretical and practical significance) of individual differences in a wide range of

academic, occupational, and social outcomes. Of interest to industrial and organizational psychologists, *g* is consistently the best single predictor of job training performance and technical job performance across a wide range of ages, settings, and domains. There is no job for which *g* is not at least a moderately strong predictor of technical performance.

For example, meta-analytic estimates place the predictive validity of *g* for technical job performance around .50 to .60 and .56 for performance in job training programs. The exact value varies depending on the nature of the job in question, however. For example, the correlation between *g* and technical performance for managerial and many information-dependent white-collar jobs is typically in the range of .50 to .61. By contrast, the correlation for manual labor jobs is typically around .25. It is the cognitive complexity of the occupation that moderates the predictive validity of *g*. In addition, *g* maintains its predictive validity across experience levels. In fact, some studies show that the predictive validity of *g* actually increases as experience increases. At first, this may seem counter-intuitive: After all, people with more experience have had the opportunity to learn more and hence acquire greater levels of job-specific knowledge and skills. All things being equal, an employee with greater experience will perform better than an inexperienced employee. However, all things are not equal. It is the ability to profit from experience that is of importance, and *g* essentially reflects the ability to learn from experience. Those with higher *g* learn faster; thus, as experience increases, differences in knowledge and skills attributable to *g* become increasing exaggerated.

Predictive Validity of Narrow Abilities

Unlike *g*, the predictive validity of narrow abilities is tied more closely to the nature of the criteria that one seeks to predict. Thus, it is more difficult to speak of generalized findings regarding the predictive validity of narrow abilities. In addition, given the robustness of *g*'s predictive validity, the value of narrow abilities has typically been gauged by their incremental validity. That is, in order to merit attention as practically significant, evidence for the incremental contribution of narrow abilities above and beyond *g* should be substantial, dependable, and related to meaningful outcomes. However, even the most optimistic interpretation of the existing empirical

literature would fall short of this standard for practical significance. That is, narrow abilities typically do not add significant amounts of incremental predictive validity above and beyond *g* in the prediction of academic or technical job performance. For example, after accounting for the variance attributable to *g*, the inclusion of the set of narrow abilities typically increases the correlation with technical job performance by less than .05. Thus, the narrow abilities, despite their psychological significance, may have only practical significance in situations in which the range of general ability has been restricted (e.g., among a group of doctoral graduate students, for whom prescreening produces significant range restriction in *g*) or in which there is a single, domain-specific criterion to be predicted (i.e., development of reading skills).

On the other hand, there are times when one is less interested in predicting between-person differences in performance and more interested in matching an individual person's profile of narrow abilities (i.e., their relative strengths and weakness) with the narrow ability demands of the work or educational environment. This corresponds to the dominant perspective within the vocational counseling literature. Indeed, it is well-known that *g* is an insufficient descriptor of work demands; occupations display distinct patterns of narrow ability demands. As such, the assessment of within-person differences in narrow abilities may be especially useful in personnel classification and academic and career counseling.

SUMMARY

Arguably, it is the potential breadth and magnitude of the impact of individual differences in cognitive abilities that makes their study of great interest to both scientists and the general public. Although scientific treatment of cognitive abilities did not appear until the late 19th century, theory development and a wealth of empirical data accumulated since then supports two conclusions: (1) The psychometric structure of cognitive abilities is best modeled as a three-tiered hierarchical structure with a general mental ability factor, *g*, at the apex, and (2) general mental ability is of great functional importance in virtually every aspect of life.

COGNITIVE ABILITY TESTS

Although there are many definitions of cognitive ability, most focus on the notion that cognitive ability is both a determinant and a product of human learning. A common definition of cognitive ability describes it as a general mental capability that involves, among other things, the ability to reason, plan, solve problems, think abstractly, comprehend complex ideas, learn quickly, and learn from experience. Given this definition, it is easy to see why cognitive ability is often used synonymously with the term *intelligence* and why it has long been an important construct for industrial and organizational psychologists.

COGNITIVE ABILITY TESTING IN INDUSTRY

Over the past century, a number of mental tests have been created to measure both general cognitive ability and specific abilities or aptitudes. In particular, such tests have been used to assess preemployment candidates in industry since the 1920s. These tests usually contain questions related to mathematical, verbal, spatial, and mechanical material and are typically delivered using paper and pencil. For example, cognitive

ability tests have been created to measure people's specific aptitude to solve math problems, read and answer questions about written material, and mentally rotate figures. Given the long history of these tests in industry, it is not surprising that there is widespread, global use of cognitive ability tests in companies for predicting on-the-job performance and a number of other important workplace outcomes.

Prediction of Workplace Outcomes

Cognitive ability tests have long been used in industry to assess preemployment candidates because of the strength with which they predict on-the-job performance for all jobs. In fact, extensive meta-analytic evidence from validity studies across a range of jobs (e.g., clerical, military, sales, and white-collar positions) makes a strong case for *g*, or general mental ability (GMA), as the single best predictor of performance. Meta-analytic studies conducted in the United States report predictive validity between GMA and performance ranging from .31 (refinery workers) to .73 (computer programmers), and meta-analytic studies from the European Community report a similar range and an overall operational validity of .62.

As evidenced by this wide range of correlations in the United States and in Europe, the value of the predictive validity of GMA for job performance varies according to the complexity of the job. For example, manual labor jobs tend to have validity coefficients around .25, whereas most white-collar jobs tend to have coefficients ranging from .50 to .60. Therefore, it is the complexity of the job that moderates the validity of GMA for predicting job performance. Along with job complexity, another factor originally thought to be related to the GMA–performance relationship is job experience. In particular, it was thought that this relationship would decrease with increasing job experience. Recent investigation, however, shows that the predictive validity of GMA is stable and does not decrease over time with increased job knowledge. This finding makes sense because GMA is believed to be the factor that turns experience into increased performance.

In addition to their use in predicting job performance, cognitive ability tests have also been used to successfully predict other important workplace criteria. For example, U.S. meta-analytic research findings show a strong predictive correlation of .62 between

GMA and training performance, whereas European findings report a correlation of .54. Meta-analytic research also shows that GMA is related to occupational attainment, though findings vary depending on whether the investigation is cross-sectional (.62) or longitudinal (.51). Cognitive ability results increase and standard deviations and score ranges decrease with increasing occupational level; in other words, it seems that those low in GMA have a more difficult time attaining high-level occupations.

To this point, only the relationship between GMA and workplace outcomes has been discussed despite the existence of specific aptitude theory, which posits that different jobs require different specific abilities and that testing for these specific abilities should increase or optimize the prediction of workplace outcomes. The reason for this omission is that specific aptitude tests measure GMA in addition to some specific ability, but it is the GMA component of these tests—not the specific aptitude (e.g., mathematical, spatial, verbal) components—that predicts workplace outcomes. In other words, it appears that assessing a candidate's specific aptitudes apart from GMA adds little or nothing to the prediction of posthire performance. One area in which specific abilities may be of importance in industry, however, is vocational counseling, where within-person aptitude differences can be useful in placing individuals in positions.

Utility of Cognitive Ability Testing in Preemployment Selection

In addition to investigating the predictive validity of GMA for important workplace outcomes, industrial and organizational psychologists have examined the utility, or practical value, of GMA compared to and combined with other common selection tests. It appears that cognitive ability tests (predictive validity of .51) should be used when there is only a single selection instrument for screening candidates. In cases in which multiple instruments are used to screen inexperienced candidates, cognitive ability tests should be used in combination with an integrity test (composite validity of .65), structured behavioral interview (composite validity of .63), or conscientious test (composite validity of .60). When screening experienced candidates, however, a combination of cognitive ability and work sample testing (composite validity of .63) may offer the most utility.

Prevalence of and Concerns About Cognitive Ability Testing in Industry

Surveys on the prevalence of GMA test batteries and specific aptitude tests in industry report that they are used at similar levels across countries. For example, it appears that approximately 16% of companies in the United States administer GMA tests, and 42% use aptitude tests. In Canada, it is reported that 43% of companies administer aptitude tests. In the European Community, surveys report that GMA test usage ranges from 6% (Germany) and 20% (Italy) to 70% (United Kingdom) and 74% (Finland), and that aptitude test usage ranges from 8% (Germany) to 72% (Spain). In addition, one survey reported that 56.2% of companies in Australia use cognitive tests.

Although these percentages indicate widespread global use of GMA and aptitude tests, their prevalence is far less than the nearly 100% global use of interviews as screening instruments. In addition, these numbers show that many companies are not using cognitive ability tests despite the accumulated evidence of their ability to predict important workplace outcomes compared to other selection instruments.

There are many reasons for these results, including the cost of testing candidates, the difficulty of administering paper-and-pencil or computerized tests under supervised conditions, the possibility of negative candidate reactions, the length of the recruiting process when tests are added, and concerns about test security. In addition, industry remains concerned about legal challenges to the use of cognitive ability tests in employment screening, as the tests are perceived as being plagued by measurement bias against protected groups. The persistence of this perception, despite enormous empirical evidence showing that professionally developed cognitive ability tests are not biased against any group, is a bit of a mystery. Although concern over measurement bias has been empirically solved, many of the issues surrounding cognitive ability testing are exacerbated by recruiting and selection processes that are increasingly being managed and delivered through the Internet under unsupervised conditions.

SUMMARY

More than 100 years of theory development and empirical investigation of cognitive ability have shown this measure to be a valid and fair predictor of

important job outcomes in companies throughout the world. Despite overwhelming evidence of its success and its strengths compared with other selection instruments, however, many companies are still not using cognitive ability tests. It is hoped that cognitive ability researchers and test developers will focus on technological advances in delivering cognitive tests and developing tests with less adverse impact that can be transported globally. These advances in cognitive ability testing will surely allow more companies to benefit from its use.

COMPARABLE WORTH

The commonly accepted definition of comparable worth is that dissimilar jobs that are of equal worth to the organization (e.g., nurses and truck drivers) should be paid the same wage. The term *comparable worth* must be distinguished from related terms, such as

equal pay for equal work. The latter term is associated with the U.S. law known as the Equal Pay Act of 1963, which requires that men and women doing essentially the same job should be paid the same unless the differences are attributable to factors such as merit, seniority, or other job-related criteria. The Equal Pay Act of 1963, then, requires that the plaintiff perform the same job as the comparison group. Comparable worth is sometimes referred to as *pay equity*. The underlying premise of comparable worth is that persistent discrimination against predominantly female jobs results in women earning consistently lower wages than men. Only by comparing different jobs in terms of their worth to the organization—and adjusting the pay of jobs held predominantly by women when necessary—can fairness be achieved.

Comparable worth advocates typically assume that market wages, as determined by salary surveys, reflect sex bias because the skills and job requirements associated with women's work (e.g., verbal skills, small motor dexterity) are inherently undervalued by the labor market. As an alternative, comparable worth proponents advocate the use of job evaluations to determine the value of an organization's jobs.

LEGAL STATUS OF COMPARABLE WORTH

Despite the appeal of the comparable worth notion, laws to regulate this concept have made minimal progress in the United States. The most significant lawsuit to invoke the comparable worth premise was *AFSCME v. State of Washington*, which was decided by the U.S. Court of Appeals for the Ninth Circuit in 1985. The plaintiffs in this case argued that the state failed to put into practice the implications of its own job evaluation study, which indicated that predominantly female jobs were undervalued. The court sided with the state of Washington, arguing that the state was merely relying on the market rate (i.e., paying what other organizations were paying for these jobs). This market argument proved to be a fatal blow to the comparable worth principle.

Since that decision, neither the courts nor the U.S. Congress have accepted the comparable worth concept. Approximately 20 states, however, have enacted comparable worth laws requiring some form of pay equity for state employees. Canada has passed pay laws that are similar to laws in the United States. The province of Ontario, one of 12 provinces in Canada,

passed the most pro-employee pay law, which became effective in January 1988. That law, referred to as the Pay Equity Act, requires companies with 100 or more employees to conduct a job evaluation to determine whether there is gender discrimination in pay across different jobs.

CONDUCTING A COMPARABLE WORTH STUDY

A typical comparable worth study comprises two steps. In the first half of the study, a job evaluation is conducted for the relevant jobs to determine their major tasks, responsibilities, and working conditions. Next, a job evaluation tool must be chosen (i.e., an off-the-shelf version) or created, and the pertinent jobs must be evaluated. Each job is assigned a quantitative value reflecting its worth to the organization. In the second half of the study, salary information is gathered from other organizations in the labor market. This salary information and the results of the job evaluation are then used to develop a mathematical formula. Job evaluation points from predominantly female jobs are entered into the formula to determine what the pay would be in the absence of discrimination.

Job evaluation, however, may be susceptible to gender bias, the very problem it is intended to ameliorate. Specifically, there may be bias in terms of the information collected about jobs, the choice of factors used to evaluate jobs (i.e., compensable factors), how those factors are defined and anchored, and how those factors are weighted. Research shows that the current salary and organizational level of a job may indirectly contribute to gender bias in a job evaluation. Despite the potential bias against predominantly female jobs even when conducting a job evaluation, comparable worth studies generally find that these jobs pay less than predominantly male jobs of the same worth.

CRITICISMS OF COMPARABLE WORTH

Critics have raised several objections to the comparable worth principle. One objection is that the implementation of comparable worth will significantly increase payroll costs; however, a recent study of eight states indicated that increasing the wages of predominantly female jobs increased payroll costs only 1% to 4%, with most increases around 3.5%.

Another criticism is that the value or worth of a particular job is in the eye of the beholder. Indeed,

research indicates that different job evaluation procedures may yield different conclusions about whether comparable worth is present; even the way in which compensable factors are weighted may affect the conclusions one draws about the degree to which comparable worth is present.

A third criticism of the comparable worth concept is that pay should be treated as a free market with as little government intervention as possible. That is, the basic principle of supply and demand should determine appropriate wages—employees are free to apply for a different job if they do not like the pay that is associated with a particular position. This argument asserts that companies should be allowed to set whatever wage they believe is appropriate for a specific job (although the Equal Pay Act of 1963 prohibits pay discrimination for men and women doing the same job) and that workers should be able to choose whatever jobs they wish (the Civil Rights Act of 1964 prohibits sex discrimination in hiring and promotions).

A fourth criticism of comparable worth is that other factors, such as unionization rates and labor market shortages, may play a role in setting salaries but are not reflected in job evaluations. Critics argue these factors are important determinants of pay and must also be considered in setting pay.

Clearly, the comparable worth notion is a complicated one. Although industrial and organizational psychology can make important contributions here, whether one accepts or opposes this concept ultimately depends on one's values and beliefs about the world of work.

COMPENSATION

The simple act of receiving a paycheck for one's job is the result of many complex processes involved in the art and science of compensation. Compensation systems are designed to comply with a large number of organizational objectives, including serving as an exchange for hourly labor, motivating behavior, and accomplishing social objectives such as covering the cost of medical insurance. The design of compensation systems and methods for distributing pay and benefits is influenced by cultural traditions and legal requirements.

Within the organizational sciences, compensation has traditionally encompassed base pay, pay raises, pay systems, benefits, the psychology of pay, and legal issues. Recently, the area of compensation has expanded to include nontraditional conceptions of pay that are often captured under the term *total compensation*. Total compensation includes not only pay and benefits but also nonmonetary rewards, such as the value of positive job characteristics (e.g., having a creative job has a positive nonmonetary value that should be seen as part of total compensation). A second change that has occurred in the area of compensation over the last 20 years is an increased emphasis on at-risk pay, variable pay, or pay for performance. Despite the importance of these two recent trends, compensation will be treated here in its more traditional fashion, although brief mention will be made of total compensation and at-risk pay.

BASE PAY

Establishing the base pay, the basic annual salary or hourly wage, for a job can be a challenge. Organizations often rely on the market, which can be assessed through market surveys. However, the market can be unstable and unreliable. Industrial and organizational psychologists have made a significant contribution to the field of compensation through their work on job analysis and job evaluation systems. Job evaluation systems, particularly the point system, provide reliable, valid methods of measuring the compensable worth of jobs through the ratings of job characteristics such as skill, effort, responsibility, and working conditions. Job evaluation systems allow for the distribution or slotting of jobs into *grades*. Jobs within a grade receive the same base pay, although

there can be fluctuations based on the step within the grade.

During the 1990s, the idea of broadbanding became more popular. Under a traditional system, there may be as many as 12 to 20 grades. Under a broadband system, there may be as few as 3 to 5 grades. Broadbanding systems are seen as allowing for greater managerial discretion and flexibility in the assignment of initial rates of base pay.

PAY RAISES

In traditional pay systems, individuals start at a certain entry pay rate. Over time, they receive pay increases. In most systems, these increases are a function of both seniority and the cost of living. Pay raises may also depend on merit. Although merit may be based on some type of objective performance criteria, it is usually operationalized based on supervisor recommendations or ratings. Thus, the merit component is heavily dependent on the perceived fairness of the performance appraisal system. In addition to individual performance, pay raises may vary based on organizational performance, organizational productivity, or market conditions.

PAY SYSTEMS

Traditional pay systems rely on the payment of a fixed annual salary or hourly wage. This may be accompanied by periodic raises based on the cost of living or on merit. Over the last 40 years, however, this traditional view of pay has been challenged. For example, the *new pay movement* emphasizes paying workers for skills (i.e., skill- or competency-based pay) as opposed to the actual duties performed on the job.

The *total compensation movement* argues that pay should be conceived as being more than just salary and benefits, including as well the psychological benefits of the job. For example, having a good leader or having a lot of autonomy could be considered part of the total compensation package because these elements of the job represent a psychological benefit.

The *variable* or *at-risk pay* approach is based on the concept that pay is often seen as an entitlement and that more of an employee's compensation dollar should be at risk and earned through effective performance. As a result, companies have begun to introduce a variety of pay-for-performance and incentive systems, including gainsharing, goal sharing, and profit sharing.

BENEFITS

Relatively little psychological research has been conducted in the area of benefits. Benefits are important to pay satisfaction overall, but the overall value of benefits tends to vary as a function of the degree to which workers need benefits. For example, younger workers tend to be more aware of their maternity benefits, whereas older workers tend to be more aware of their retirement benefits. Thus, the value of benefits is likely to shift as a function of both the culture of the worker's generation and the point in his or her career path.

PSYCHOLOGY OF PAY

It may be somewhat surprising that industrial and organizational psychologists have not paid more attention to the psychology of pay. This lack of attention is partly a result of the humanistic-organizational movement of the 1950s and 1960s. Nevertheless, there are some theories aimed at explaining pay processes and pay satisfaction.

Three major theories attempt to explain satisfaction with distribution rules: *equity theory*, *equality theory*, and *utility theory*. In recent years, *justice theory* has also emerged as a major research framework. Justice theory argues that it is not just the fairness of the distribution that matters but also the fairness of the procedures used to make decisions. A major theoretical contribution to our understanding of executive pay is *agency theory*, which argues that stockholders use large incentives to motivate their agents (executives) to act in the best interest of the stockholders.

Major contributions have been made in the area of pay satisfaction measurement. The main facets of pay satisfaction are pay level, raises, benefits, and administration.

LEGAL ISSUES

As in most areas of human resources in the United States, federal and state laws have had a huge impact on the practical design of compensation systems and on the topics studied by researchers. Some of the laws that affect compensation in the United States include the Fair Labor Standards Act of 1938, the Equal Pay Act of 1963, and Title VII of the Civil Rights Acts of 1964 and 1991. Unions also have a major impact on pay systems.

During the 1970s, the issue of sex discrimination in pay was much debated. This debate, referred to as the *pay equity* or *comparable worth* debate, prompted a great deal of research by industrial and organizational psychologists on the psychometric properties of job evaluation systems and gender issues in pay systems.

SPECIAL GROUPS AND TOPICS

Some groups, such as salespeople and executives, have special compensation systems. For example, some salespeople work on 100% commission based on their sales. Executive pay in the United States has become a controversial topic because of the large differences between worker and executive pay and the apparent disconnect between firm performance and executive pay.

The increased globalization of companies has also led to special compensation challenges. As with other types of pay, organizations have attempted to place limitations and controls on the amounts spent on expatriate pay.

One of the most interesting challenges to traditional compensation arose during the late 1990s as a result of the rise of virtual companies and e-jobs. A question that may have to be answered in the future is how to best compensate people working for virtual companies.

CONCLUSION

Pay is a complex process that is influenced by culture, society, and the law. At the individual level, pay satisfaction is important to job satisfaction, organizational commitment, and turnover intentions. Although individuals do not necessarily stay with an organization because of pay, it is clear that a major reason individuals leave organizations is the receipt of generous pay offers from other companies. Organizations continue to strive to develop pay systems that will give them a competitive advantage, although it is unclear whether pay satisfaction causes organizational financial performance or whether the financial performance of organizations leads to increased pay satisfaction.

COMPETENCY MODELING

Competency modeling is a method of collecting and organizing job information and worker attributes into broad *competencies*. Competencies are descriptions of the characteristics and qualities that a person needs to possess to perform a job successfully. Although the practice of competency modeling is relatively new to the field of industrial and organizational psychology, the idea of defining and assessing competencies is not. In 1966, Blake Root and Ray Roberts described the competencies needed for training directors. In 1972, J. M. Dornan outlined five primary competency areas that managers should develop to be maximally effective. In 1973, a study by David McClelland suggested that psychologists focus their efforts on assessing an individual's competence at tasks rather than measuring their intelligence. Today, industrial and organizational psychologists see competency modeling as an extension of job analysis in a more pragmatic business context, in which in-depth analysis is neither supported nor warranted.

COMPETENCIES

A competency is an attribute of an individual that is needed to meet job requirements successfully. For example, a required competency for a sales executive could be a *drive for results*. A well-designed

competency model describes specific performance standards and identifies behaviors that anchor a competency to levels of performance. To perform well in a job, an individual typically must be proficient in a number of competencies. Although there is no hard-and-fast rule as to how many competencies may be linked to a job, typically a range of 8 to 12 competencies should be sufficient and practical for any given job.

COMPETENCY MODELING

A *competency model* is a set of competencies that are necessary for effective performance. Competency models typically cover a broader range of jobs than traditional job analysis and may be divided into job levels that cut across an organization (e.g., individual contributor, first-level manager, midlevel manager, senior manager). Competency models often explicitly include a consideration of the values, strategies, and objectives of the organization. Partly because of the strategic significance of competencies, many organizations adopt a critical set of *core competencies* that are required of the organization's members across all jobs and all levels. Core competencies are typically embedded within all of the competency models for an organization and tied to the organization's culture, viability, and identity.

Competency Modeling Processes

There are a variety of approaches to developing competency models. One method involves the use of focus groups conducted with subject-matter experts. This process provides the developer with opportunities to interact with incumbents, supervisors, and organizational leaders to retrieve rich, qualitative input and gain support and buy-in for the resulting competency models. Behavioral event, or critical incident, interviews may also be conducted with job experts. These interviews allow the interviewer to gain in-depth, behaviorally based information about what is required of an individual on the job and which key behaviors drive success and failure. Developers of competency models may also choose to use questionnaires, which tend to provide more quantitative information and can be used for competency models that require more rigorous development (e.g., for selection purposes). Although traditional job analysis processes are considered more rigorous than competency

modeling processes, if the objective is to link jobs to organizational goals and strategies, a competency modeling approach is generally preferred.

Competency Modeling Outcomes

Competency models may be developed and implemented to meet a variety of organizational objectives. The reason the competency model is being developed often predicated the manner in which it is organized and presented. Some organizations opt to develop a single, broad-based, organization-wide competency model. Others choose to develop job-specific competency models for each position or role within the organization.

Broad Competency Models

When an organization-wide approach to competency modeling is used, technical and functional distinctions between job roles and positions are not included in the overall competency model. The organization may choose to add additional competencies by level or by individual functional groups. Another broad competency model approach involves the development of key competency models divided by organizational levels, such as individual contributor, first-level manager, midlevel manager, and senior manager. The broad competency model approach can aid in organization-wide succession planning and employee development efforts because the competencies needed at all levels of the organization and in all positions are transportable.

Job-Specific Competency Models

A competency model may also define a set of competencies required for a more narrowly defined job or position. When organizations define talent requirements for a specific part of the business, these models are very helpful. Job-specific competency models often include functional and technical competencies, and the behavioral standards are even more specific to the individuals performing the jobs. The downside is that developing job-specific competency models across the business can be time intensive and costly. One way to handle this challenge is to develop core competencies that apply across a range of jobs and leave it up to individual business units or functional areas to define more job-specific competencies.

USES OF COMPETENCY MODELS

Competency models can be thought of as an infrastructure on which an organization can base selection, development, and evaluation efforts. Competency models and performance standards can be used to structure the following talent management systems:

- Performance appraisal systems, in which competencies are included along with specific results of performance; results may be seen as the *what* of performance, and competencies define *how* the results were achieved
- Multirater (360-degree) performance feedback systems, in which competencies and performance standards are rated by colleagues
- Individual assessment processes and assessment centers, in which competencies and performance standards are used to organize evaluation and feedback
- Training and development programs, in which competencies serve as an organizing framework to ensure there is adequate coverage of a range of critical skills for the business
- Organizational succession planning programs, in which potential successors are identified and groomed based on their level of proficiency, measured against organizational competencies

Finally, organizations may use competency models as a springboard for organizational change. A public utility organization (telephone, electricity, natural gas), for example, which previously thrived during times of government regulation and limited competition, might develop a new competency model for the organization to prepare it for the future challenges of deregulation and increased competition. The competency model it develops could incorporate competencies that address customer service expectations and cost-reduction efforts. Though these constructs may be new to many of the organization's members, by beginning to evaluate and assess employees based on this "stretch" competency model, the organization will drive home the importance of the new standards of performance. In this manner, the strategic competency model will drive forward the change that needs to occur in the organization at a specific, behavioral level.

COMPRESSED WORKWEEK

In compressed workweek schedules, the workweek is compressed into fewer than five days by increasing the number of hours an employee is required to work each day. The most common form of compressed workweek in the United States is the four-day, 40-hour workweek (4/40). Usually employees will take either Friday or Monday off, extending their weekend to three days. However, because some compressed workweek schedules are implemented because of long distances between the worker's home and workplace (e.g., oil industry, merchant shipping), having a three-day weekend is not necessarily a part of a compressed workweek schedule. Recently, variations of the typical 4/40 schedule (e.g., 3/36, 3/38, and 3/40) have been adopted by some organizations. The Society for Human Resource Management's 2001 Benefits Survey showed that 31% of respondents offered compressed workweeks.

The literature indicates that compressed workweek schedules are most commonly used in manufacturing settings. This is probably attributable to two reasons. First, because compressed workweek schedules still require all workers to attend work at the same time, they meet the interdependence requirement of assembly line settings. Second, manufacturing organizations typically do not serve retail customers and thus do not require employees to be present at regular time intervals (e.g., Monday to Saturday).

When considering the use of compressed workweeks, employers must keep in mind that the workweek can only be compressed to the extent that an employee's daily working hours do not exceed any legal limit. Although the United States does not have any federal law that caps the number of working hours, many state and industry-specific laws do impose a cap. For example, truck drivers are only allowed to drive 11 hours per work period. Many other industrialized countries have federal caps that

limit the use of certain types of compressed workweek schedules (e.g., a 3/40 schedule). For example, Germany and Japan have a 10-hour legal limit on the number of hours that can be worked on any given day.

Compared with other alternative work schedules (e.g., flexible work schedules), compressed workweeks are not always desired by employees and sometimes are even less desirable than the normal 5/40 work schedule. Research has found that younger employees favor compressed workweeks, whereas older workers do not. In addition, employees who favor compressed workweeks tend to occupy lower-income or lower-level jobs.

PERCEIVED BENEFITS OF A COMPRESSED WORKWEEK

From the employer's perspective, compressed workweeks allow for longer working hours and thus lower start-up expenses. For example, in certain manufacturing industries, there is often a start-up expense each time a production line is put into use. By having employees work longer hours for fewer days, the overall daily start-up costs are reduced. For employees, compressed workweeks allow workers to enjoy larger blocks of leisure time and reduce transport expenses and overall commuting time because they work fewer days.

Two models have been developed to explain how compressed workweek schedules may affect employee and organizational outcomes. The first model uses a biological perspective focusing on the circadian rhythms of individuals. The hypothesis of this approach is that there are only a few hours each day when employees can perform at optimal levels. The second theoretical model is the job characteristics theory. This model proposes that there are core characteristics of each job (e.g., the amount of job autonomy) that induce positive psychological states, which, in turn, lead to positive effects on work-related outcomes. Using these models, a theoretical argument can be made about how compressed workweek schedules affect the most important organizational outcomes: productivity and performance, absenteeism from work, and job satisfaction or satisfaction with one's work schedule.

The hypothesis of the circadian rhythm approach is that employees can perform at optimal levels for only a few hours each day. Thus, when employees work

longer hours each day (an essential component of compressed workweeks), the amount of time they are working at suboptimal levels should increase. Furthermore, working longer hours should lead to an increase in fatigue, which also could negatively affect performance. Finally, if increased fatigue is associated with increased employee stress, then one would also expect to see a decrease in performance. Theoretically, then, the implementation of a compressed workweek schedule can be expected to lead to lower employee performance and productivity.

With respect to attendance at work, the introduction of a compressed workweek schedule should give employees more discretionary time, which should increase attendance. Employees who enjoy three-day weekends should be better able to balance work and nonwork demands. Being able to respond to work and nonwork conflicts more easily should reduce stress, and decreased employee stress has been linked to decreased absenteeism. Thus, the introduction of a compressed work schedule can be expected to have positive effects on absenteeism from work.

It has been hypothesized that a compressed workweek should increase an employee's level of autonomy. The job characteristics model predicts that higher levels of job autonomy lead to higher job satisfaction. Thus, job satisfaction and satisfaction with one's schedule should be positively affected by the introduction of a compressed workweek schedule.

RESEARCH ON COMPRESSED WORKWEEKS

Narrative summaries of research on compressed workweeks have concluded that the effects of compressed workweek schedules on performance are mixed: Performance either improves or stays the same after the implementation of a compressed workweek schedule. However, some studies have found that performance does decrease, as predicted by the circadian rhythm model. Research that found a decrease in productivity also shows that fatigue does seem to play a role in this decrease. Specifically, as fatigue increased, performance decreased. These same narrative reviews also concluded that absenteeism does decrease following the implementation of a compressed workweek, although the results are mixed (i.e., some studies found no change in absenteeism, whereas others found a reduction). Finally, with

respect to job satisfaction and satisfaction with one's schedule, the narrative reviews concluded that the results are mixed (i.e., sometimes they increase and sometimes they decrease).

A quantitative review of the literature (i.e., a meta-analysis) also found that compressed workweek schedules positively affect supervisor performance ratings, job satisfaction, and satisfaction with one's work schedule but do not affect productivity (a more objective measure of performance). Finally, and perhaps most surprising, the meta-analysis found that absenteeism is not affected by a compressed workweek schedule. In this meta-analysis, the time since the schedule intervention (i.e., how long after the introduction of the compressed workweek outcomes were measured) was also tested as a moderator of the effect of compressed workweek schedules. However, the results suggest that the effects of compressed workweeks do not change over time.

SUMMARY

A recent quantitative review of the literature suggests that compressed workweeks have positive effects on supervisor-rated performance but not on productivity; therefore, an organization's evaluation of these schedules with respect to performance depends on which of these criteria it puts more credence in. However, at the very least, an organization should not expect a decrease in performance with the introduction of a compressed workweek schedule. This, of course, goes against the hypotheses put forth by the circadian rhythm approach and suggests that future research is needed to explain this result. It also appears from the quantitative review that, on average, employees respond positively to compressed workweeks, although great variation is found across companies. Thus, an increase in job satisfaction and satisfaction with one's work schedule should not be assumed. Whether these attitudinal measures increase depends on the makeup of the organization's employees (e.g., older employees seem to dislike compressed workweeks). Finally, although an increase in attendance is an assumed benefit of introducing a compressed workweek, the quantitative review suggests this is not the case. This result goes against popular perceptions of compressed workweek schedules as well as the hypotheses that reduced employee stress resulting from more discretionary time will lead to less absenteeism. Thus, future research is needed to better

understand why compressed workweeks do not seem to reduce absenteeism.

COMPUTER ADAPTIVE TESTING

See COMPUTER ASSESSMENT

COMPUTER ASSESSMENT

Computer assessment, Web-based assessment, and computer adaptive testing (CAT) all refer to a classification of personnel instruments that use computer technology for the purposes of selection and assessment. The most general of these terms, computer assessment, refers to any assessment instrument that is presented using a computer interface. Web-based assessment is a specialized form of computer assessment that relies on features of the World Wide Web for the administration of the assessment. Finally, CAT uses the computer technology to administer tests in an

unconventional manner. Essentially, this form of testing adapts to the test taker based on his or her past responses to produce a testing experience that is tailored to a particular individual.

COMPUTER ASSESSMENT

The simplest form of computerized assessment consists of taking a paper-and-pencil instrument and presenting the items on that assessment on a computer. These tests are often referred to as *page-turner tests* because the technology of the computer is used to move test takers from one item to the next, like turning from page to page in a traditional paper-and-pencil assessment. However, more extensive utilization of computer technology can be integrated into an assessment system. For example, computers allow test developers to include multimedia elements such as audio and video files in their assessments. In addition, computer technology affords the opportunity for more interactive assessment than is possible in the paper-and-pencil format—for example, an assessment could include a computerized “in basket” that responds to an individual’s actions or provides information when queried.

WEB-BASED ASSESSMENT

Web-based assessment takes the process of computerized assessment one step further by incorporating the Internet into the assessment process. The capabilities of the Internet allow for enhanced flexibility in the assessment process. The Internet enables assessments to be administered in a wide variety of locations and at different times without the need for specialized software. Web-based assessment permits test takers to complete assessment batteries in the comfort and privacy of their own home at a time that is most convenient for them without needing a proctor to administer the test. Internet technology also creates opportunities for unique assessments that are not possible using computers alone. For example, Web-based interviewing can use videoconferencing technology to conduct interviews that fall somewhere between face-to-face and telephone interviews in terms of interactivity.

COMPUTER ADAPTIVE TESTING

Computer adaptive testing presents a markedly different application of computer technology in assessment.

Conventional tests typically consist of a set number of items that all test takers are exposed to. Because most tests contain a mixture of easy, moderately difficult, and difficult items, some test takers are exposed to items that are inappropriate for their ability. For example, high-ability test takers are required to answer some very easy items, and low-ability examinees are forced to wrestle with some extremely difficult items. Because high performers tend to get all of the easy items correct, these items do not help to differentiate among high-ability examinees. The same is true for low-ability examinees, who have little chance of success on difficult items. Because these inappropriate items do not differentiate among test takers of similar ability, a more efficient solution would be to ask test takers to respond only to items that are appropriate for their ability level. This is where CAT comes into play.

The process of CAT is as follows: An examinee responds to an initial item that is presented. The adaptive test then uses a statistical model called *item response theory* to generate an estimate of the examinee's ability, and based on this estimate, the computer selects an item of appropriate difficulty to be presented next. This procedure continues iteratively after each item has been answered until some criterion for stopping the test is reached, such as answering a pre-specified number of items, reaching a time limit, or achieving a certain level of measurement precision. Because the presentation of items is tailored to examinees, test takers no longer have to answer questions that are extremely easy or exceedingly difficult for them. Because inappropriate items have been eliminated, adaptive testing procedures are much more efficient. In addition, because the items presented are tailored to a particular individual, CAT provides a more precise estimate of a test taker's true score.

This process of tailoring items to a particular examinee creates a testing process that is quite unlike conventional tests. An obvious result of CAT is that all test takers do not receive the same items. Unlike conventional tests, which administer a fixed set of items to all examinees, CAT presents items based on individual response patterns. Thus, two examinees taking the test in the same place and at the same time might receive two completely different sets of questions. Computer adaptive tests also differ in the way an individual's score is calculated. On conventional tests, an individual's test score is determined by the number of

questions he or she answered correctly. However, on an adaptive test, scores are not based solely on the number of items answered correctly but also on *which* items were answered correctly. Test takers are rewarded more for answering difficult questions correctly than for answering easy questions correctly. Unlike traditional paper-and-pencil tests, which allow test takers to skip items and return to them later, review their answers to previous items, and change answers to items already completed, adaptive tests usually do not permit any of these actions. Instead, test takers must advance through adaptive tests linearly, answering each question before moving on to the next one, with no opportunity to go back.

ADVANTAGES

The integration of technology and assessment confers a number of advantages, the most obvious being the potential for new and different types of assessment. Computerized multimedia or interactive assessments have the potential to increase the perceived realism of the assessment, thereby improving face validity and even criterion-related validity. In addition, novel performance indexes can be collected using computer technology, such as response latencies, which may further enhance validity or reduce adverse impact. In the case of CAT, these assessments are considerably more precise and efficient, taking one third to one half the time of a conventional test. Adaptive tests also provide increased test security. Because test takers receive items that are tailored specifically to them, it is virtually impossible to cheat. Similarly, conventional computerized tests may be more secure because there are no test forms that can be compromised.

Another advantage of computerized assessments is their ability to provide instantaneous feedback to test takers regarding their performance. Despite the large up-front costs of technology, computerized assessments can be economically advantageous. Because there are no printing costs, the cost of creating new tests or switching to a different test form is negligible. No manpower is required to score the assessments or compile the data from individuals' responses, making the results less prone to error. In the case of Web-based assessment, the cost of test proctors can be eliminated. Web-based assessment confers additional advantages and cost savings because it can be administered anywhere Internet access is available.

CRITICAL ISSUES

As with any new technology, there are a number of potential pitfalls that must be avoided to make full use of these techniques. One major concern with the use of technologically sophisticated assessments is adverse impact, especially because of the known disparity in access to technology among different groups. Test security must also be managed differently when technology is involved. Computerized assessments can enhance test security because there is no opportunity for test forms or booklets to be compromised. However, test administrators must protect the computerized item banks as well as the computerized records of individuals' responses. Unproctored Web-based assessment creates the additional security dilemma of not knowing exactly who might be taking a particular assessment device or whether the respondent is working alone or getting assistance.

It is important to consider the measurement equivalence of the new procedure. The concept of measurement equivalence is concerned with whether a test administered using a computer will produce a score that is equivalent to the score one would obtain on the paper-and-pencil version of that test. Research shows that tests administered adaptively are equivalent to conventionally administered assessments. Cognitive ability tests also produce similar scores regardless of whether they are administered in paper-and-pencil or computer format. However, the equivalence of scores decreases dramatically on speeded tests (tests that have stringent time limits). Care should be taken when computerizing noncognitive assessments because the measurement equivalence of noncognitive batteries remains relatively unknown.

The problem of measurement equivalence also extends to proctored versus unproctored computerized tests. Web-based procedures afford more opportunities for assessments to be completed in an unproctored setting, but the question remains whether scores obtained without a proctor are equivalent to those that might be obtained in a supervised administration.

Finally, because technologically sophisticated assessment procedures are very different from traditional procedures that applicants are accustomed to, test takers' reactions to the procedures must be taken into account. This is particularly true for testing procedures that use novel item types or for CAT, which uses an unfamiliar testing procedure.

CONCLUSIONS

Computerized assessment, Web-based assessment, and CAT provide a number of advantages over conventionally administered assessments and will likely dominate the selection and assessment landscape in the future. However, care must be taken when implementing these technologically sophisticated assessments to ensure that the reliability and validity of procedures is established and maintained.

CONFIDENCE INTERVALS/HYPOTHESIS TESTING/EFFECT SIZES

Inferential statistics play a critical role in assessing whether training, tests, or other organizational interventions have an effect that can be reliably expected based on data collected from samples of organizational members. For example, the score from a selection test administered to a sample of 100 job applicants could be correlated with the test takers' subsequent performance ratings to determine how well the test predicts job performance. If we find that the correlation (r) calculated from the sample's test scores and

ratings is .25, we are left with several questions: How does a sample-derived correlation of .25 compare with the correlation that could be obtained if we had test and ratings data on all cases in the population? How likely is it that we will get the same or approximately the same value for r with another sample of 100 cases? How good is an r of .25? Confidence intervals, significance testing, and effect sizes play pivotal roles in answering these questions.

CONFIDENCE INTERVALS

Using the foregoing example, assume that the correlation (ρ) between the test scores and ratings is .35 in the population. This ρ of .35 is called a *parameter* because it is based on a population, whereas the r of .25 is called a *statistic* because it is based on a sample. If another sample of 100 cases were drawn randomly from the same population with an infinite number of cases, the r calculated using test and ratings data from the new sample would probably differ from both the ρ of .35 and the r of .25 calculated for the first sample. We can continue sampling and calculating r an infinite number of times, and each r s would be an estimate of ρ . Typically, r would be distributed around ρ , with some being smaller than .35 and others being larger. If the mean of all possible r s equals ρ , then each r is said to be an unbiased estimate of ρ . The distribution of r is called the *sampling distribution* of the sample correlation, and its standard deviation is called the standard error (SE). The SE of r can be calculated as

$$SE = \frac{(1 - \rho^2)}{\sqrt{N}} \quad (1)$$

where N is the sample size. Notably, as N increases, SE decreases.

A confidence interval (CI) is the portion of the sampling distribution into which a statistic (e.g., r) will fall a prescribed percentage of the time. For example, a 95% CI means that a statistic will fall between the interval's lower and upper limits 95% of the time. The limits for the 95% CI can be calculated as follows:

$$95\% \text{ CI} = \rho \pm (1.96) SE \quad (2)$$

If a 99% CI were desired, the value 2.58 would be substituted for 1.96. These two levels of CI are those most commonly used in practice.

Let us compute CI using $\rho = .35$, $N = 100$, the common assumption that the distribution of r is normal, and Equation 1, $SE = (1 - .35^2)/\sqrt{100} = .088$. Using Equation 2, the lower limit is $.35 - (1.96)(.088) = .178$, and the upper limit is $.35 + (1.96)(.088) = .472$. This example CI can be interpreted as follows: If an infinite number of random samples of 100 each were drawn from the population of interest, 95% of the r s would fall between .178 and .472, and 5% would fall outside the CI .

HYPOTHESIS TESTING

In the previous example, ρ was known, but this is rarely the case in practice. In such cases, the investigator may use previous research findings as a basis for assuming that ρ is .40. Because we now have the necessary information, we can compute the 95% CI as follows: $SE = (1 - .40^2)/\sqrt{100} = .084$. The CI lower limit is $.40 - 1.96(.084) = .235$, and the CI upper limit is $.40 + 1.96(.084) = .565$. According to the definition of 95% CI , correlations between test scores and ratings, based on samples of 100 randomly drawn from a population with $\rho = .40$, would fall between .235 and .565 95% of the time and outside that range or interval 5% of the time. Because the r of .25 is inside the 95% CI , it is very likely that the sample at hand came from a population in which ρ is .40. That is, we are 95% confident that our sample came from a population with a ρ of .40, but there is a 5% chance that it did not.

In practice, it is not easy to come up with a reasonable hypothesis about a population parameter. Yet a practitioner may want to say something of value about a statistic. In our example of $r = .25$, a practitioner may want to know whether it came from a population with $\rho = .00$. The rationale is that if it can be shown with a certain degree of confidence that the sample with $r = .25$ is unlikely to have come from a population with zero correlation, then that information would have practical utility—that is, the test is very likely to have nonzero validity in the population of interest. This is commonly referred to as *null hypothesis testing*. If $\rho = .00$, then the SE for a sample of 100 cases is $(1 - .00^2)/\sqrt{100} = .100$, and the 95% CI is $(-.196, +.196)$. Our r of .25 falls outside this interval, and therefore there is a 95% chance that our sample did not come from a population with $\rho = .00$. That is, the null hypothesis of $\rho = .00$ is unlikely given that the r is .25; some would say that the null hypothesis is rejected

with 95% confidence. There is, however, a 5% chance that our sample came from a population with $\rho = .00$. Because this probability is small, we may assume that ρ is different from zero and conclude that the test is a valid predictor of performance ratings.

We did not say, however, that the null hypothesis was proved or disproved. According to Sir Ronald Fisher, the eminent statistician who popularized the null hypothesis, the null hypothesis is never proved or established, but it may be disproved as we obtain data from more samples. Although professionals debate whether null hypothesis testing is useful, most researchers agree that *CI*s and effect sizes probably provide more information than null hypothesis testing.

APPLICATION OF CONFIDENCE INTERVALS

The assumption underlying Equation 1 is that we know or are willing to hypothesize the value of ρ . Making an assumption about ρ leads us into hypothesis testing. One way to avoid this is to develop *CI*s by using r as our best estimate of ρ . When we use r as an estimate of ρ , Equation 1 becomes

$$SE = \frac{(1-r^2)}{\sqrt{N-1}} \quad (3)$$

When r and N are known, Equation 3 can be used to compute *SE* and *CI*. Given $r = .25$ and $N = 100$, $SE = (1 - .25^2)/\sqrt{100 - 1} = .094$. The *CI* lower limit is $.25 - (1.96)(.094) = .066$, and the *CI* upper limit is $.25 + (1.96)(.094) = .434$. Therefore, the 95% *CI* is (.066, .434). We cannot say with 95% confidence that the unknown ρ falls within this interval, but we say that ρ is likely contained in this interval without attaching any probability to that statement. Is such a statement of any help? Yes, it is. If an investigator generated an infinite number of random samples from the same population, computed a 95% *CI* each time, and concluded that ρ falls within that *CI*, the investigator would be correct 95% of the time in the sense that 95% of the *CI*s will include ρ . For a given *CI*, either ρ is or is not in it. But if we consider an infinite number of *CI*s, 95% of them will include ρ .

In the preceding sections, we only used correlations to describe and illustrate *CI*s and hypothesis testing. These techniques and interpretations are equally valid for means and other statistics.

EFFECT SIZES

Effect sizes (ESs) play an increasingly important role in the behavioral sciences, especially given their emphasis in meta-analysis. An ES, such as r or the standardized difference (d), reflects the degree to which a predictor measure is related to an outcome measure or the degree of difference between outcome scores for an intervention group and a comparison group.

Consider a situation in which an intervention group of randomly chosen employees received sales training and a comparison group did not. After one year, the trained and comparison groups were selling, on average, 345 units ($M_I = 345$) and 275 units ($M_C = 275$), respectively. The standard deviation (*SD*) of units sold equals 70 for both groups. The difference between the average number of units sold is 70 ($M_E - M_C = 345 - 275 = 70$). This means that the trained group did better than the comparison group. Suppose that the same marketing technique was used with a different product in a different organization in which the trained group sold an average of 15 units and the comparison group sold 12 units. Again, the *SD* of units sold is the same in both groups and equal to 2. The mean difference is 3 ($15 - 12 = 3$).

Even though the trained groups did better than the comparison groups, it is difficult to tell whether the training was more effective for one product than for the other because the difference measures are not comparable. In the first example, the units sold were automobiles, and in the second example, the units sold were mainframe computers. If we were to run a test of the null hypothesis, we would probably find that the two mean differences (70 and 3) were significantly different from zero. This still would not help a practitioner assess whether the training was more effective for one product than another. One currently popular method of doing so is to express the gain in sales in both scenarios on a common metric. A common ES metric is d :

$$SE = \frac{M_E - M_C}{SD} \quad (4)$$

The d metric is like a z -score metric, and it is comparable across scenarios; this is generally not true for mean scores or mean score differences. In the scenario involving automobiles, the ES is 1 ($[345 - 275]/70$), which means that the trained group sold at a level 1

SD above the comparison group. Similarly, in the scenario involving mainframe computers, the *ES* is 1.5 ($[15 - 12]/2$), which indicates that the trained group performed 1.5 *SDs* above the comparison group. Because the *ES* metrics are comparable, we can conclude, all else being equal, that the training is more effective for selling mainframe computers than automobiles. The mean differences alone (70 versus 3) would not allow us to make that statement. Finally, we can calculate a pooled *SD* (the weighted average of the two *SDs*) and use it in Equation 4 when the separate *SDs* are different.

Another *ES* metric is *r*. Because *r* varies between -1 and $+1$, values of *r* can be compared without transforming them to another common metric. Most statistics can be converted into *ESs* using formulas found in the works given in the Further Reading section. These references also provide guidelines for combining *ESs* from many studies into a meta-analysis and determining whether an *ES* is small, medium, or large.

We have only touched on confidence intervals, hypothesis testing, and effect sizes. Readers should consult the references given in Further Reading for additional guidance, especially in light of the current emphasis on confidence intervals and effect sizes and the controversy over null hypothesis testing.

CONFIRMATORY FACTOR ANALYSIS

See FACTOR ANALYSIS

CONFLICT AT WORK

The literature on conflict at work is an extensive body that can be divided into two research streams. Some studies focus on the effective management of conflict, whereas others emphasize the emergence of conflict at work. The latter group of studies is pertinent to our understanding of the concept of conflict at work, its antecedents, and its consequences. Overall, studies demonstrate that some personality traits may be important antecedents of conflict. Although conflict can be measured across organizational levels, much of the research has focused on the interpersonal and intragroup levels and suggests that its outcomes affect both organizational effectiveness and personal well-being. Furthermore, conflict is a key construct in the recent work of occupational stress researchers, in which it is regarded as a leading social stressor.

A FRAMEWORK FOR UNDERSTANDING CONFLICT

Conflict has been defined in many ways across many studies, making it difficult to agree on one clear conceptualization of the construct. Nevertheless, researchers agree on certain definitional properties—for example, that at least two parties must be involved in order for conflict to arise. Recent work has advanced our understanding of the definitional components of conflict. Specifically, Henri Barki and Jon Hartwick tested a framework for conflict that consists of behavioral, cognitive, and affective components. In this framework, the behavioral component of conflict is reflected in the interference of one party with the objectives of another. The cognitive component refers to disagreement between the parties and reflects a discrepancy between the parties' interests, needs, or objectives. Finally, the affective component refers to the negative emotional states associated with the experience of conflict at work. This conceptualization of conflict supports a multiple-theme perspective in which all three components must be present in order for the situation to constitute a conflict.

Conflict can be further categorized according to two widely accepted sources: task and relationship conflict. *Task conflict* refers to conflict over policies, distribution of resources, or ways of completing a task. *Relationship conflict* refers to conflict emerging from personality clashes or emotionally charged interactions with others. Researchers such as Karen A. Jehn, Robin L. Pinkley, and Alan C. Amason support this distinction between sources of conflict. Hence, conflict can be conceptualized as comprising three definitional components (interference, disagreement, and negative emotion) and as being one of two types (task or relationship).

METHODOLOGICAL ISSUES IN CONFLICT MEASUREMENT

Because of discrepancies in construct definition, measures of conflict are often created for the purpose of a specific study. Often, these measures lack sound psychometric properties. In fact, even widely used conflict measures that have reliability and validity support suffer from an incomplete conceptualization of the construct. For example, Jehn's intragroup conflict measure differentiates between task and relationship conflict but measures mostly the disagreement component of conflict. M. Afzalur Rahim's measure (ROCI-I), though it assesses the amount of intragroup, intrapersonal, or intergroup conflict, does not differentiate between sources of conflict. To advance our understanding of the impact of conflict on organizational functioning, a comprehensive measure of conflict is needed.

PERSONALITY AND THE EXPERIENCE OF CONFLICT

There is some evidence that individuals who are high in specific dispositional traits are likely to experience—or at least perceive—more conflict at work. For example, individuals who are high in trait anger, which is a tendency to perceive situations as inciting feelings of anger, report experiencing more conflict at work. Similarly, longitudinal research shows that high type A individuals report more conflict. Trait anxiety and negative affectivity have also received some attention in relation to the experience of conflict. Again, results indicate that individuals high in these two traits report experiencing more conflict. Locus of control, or the

general belief that one's actions or external forces control outcomes, is also associated with the experience of conflict. These studies, however, are less conclusive: There is some support for the notion that externals report more conflict, but findings also suggest that internals are more reactive to conflict.

CONFLICT AND ITS OUTCOMES

Studies that do not differentiate between the two sources of conflict (task and relationship) consistently report negative outcomes associated with the experience of interpersonal conflict in the workplace. The same is not true of studies that distinguish between sources of conflict. The latter research supports the notion that positive outcomes are associated with moderate amounts of task conflict. For the purpose of organization, the negative personal and organizational outcomes of conflict at work will be presented first, followed by the positive consequences of conflict.

Conflict and Personal Well-being

Negative consequences to personal well-being have been reported as a result, at least in part, of conflict at work. One consequence that has received considerable support is depression. A consistent positive correlation exists between the frequency of conflicts experienced at work and depressive symptoms. Negative affective reactions, including anger, annoyance, and frustration, have also been repeatedly associated with conflict. These findings may have serious implications given the role that negative emotions play in human immune function and the production of cortisol.

Somatic complaints, or self-reported physical symptoms, have also been associated with interpersonal conflict at work. In these studies, employees who reported more conflict also reported experiencing more somatic symptoms. Furthermore, burnout and life dissatisfaction have been shown to positively correlate with the experience of organizational conflict.

Conflict and Organizational Outcomes

The literature on conflict emergence suggests that conflict can have detrimental consequences on organizational effectiveness. For example, it has been

shown that employees who perceive more conflict are less satisfied with their jobs. These findings were consistent for both relationship and task conflict when satisfaction with the group was the criterion of interest.

Conflict can also affect organizational functioning through turnover and counterproductivity. In fact, turnover intentions are reported to be higher for employees who experience more conflict. Given that turnover intentions are a good indicator of actual turnover, conflict can be said to have bottom-line cost implications for organizations. Counterproductive behaviors, or behaviors aimed at hurting the organization or the individuals who are a part of it, are the focus of much research in the occupational stress literature. Interestingly, self-report and cross-source data support a positive correlation between the frequency of conflict at work and counterproductive work behaviors. It is estimated that the cost of counterproductive behaviors, including theft, lost productivity, and aggression, may be as much as \$200 billion per year.

Performance can also suffer because of conflict in organizations. These findings are particularly true for the occurrence of relationship conflict, and they are more complex when the conflict is task related. As a result, recent literature has classified relationship conflict as detrimental to group performance, whereas task conflict is considered beneficial to organizational functioning.

Conflict and Its Benefits

Although recent meta-analytic work has questioned whether task conflict results in positive outcomes, several studies suggest that it does. This is particularly true for groups with nonroutine tasks in which a moderate amount of task conflict has been shown to improve performance. Decision quality has also received attention in the conflict literature and may be treated as an indicator of group performance. Task conflict relates to better decisions and decision quality. Furthermore, task conflict is associated with the conception of ideas, effective use of resources, and task completion. Nevertheless, maximizing the positive outcomes of conflict is not as simple as increasing task conflict while eliminating relationship conflict because the two are positively correlated. Instead, organizations must develop effective conflict management systems to benefit from task conflict.

CONFLICT AND STRESS

In recent years, occupational stress researchers have turned their attention to less widely studied stressors, such as interpersonal conflict at work. From this body of research, it is possible to conclude that interpersonal conflicts are a leading source of stress for employees across age-groups, cultures, and industries. Furthermore, studies have shown that employees perceive conflict at work to be more vexing than traditionally studied stressors, such as role conflict and ambiguity. Consequently, Paul E. Spector and his colleagues proposed a model of interpersonal conflict (based on an occupational stress perspective) in which conflict is treated as a stressor that may result in a variety of behavioral, physiological, and psychological strains.

CONCLUSION

Given the impact that conflict at work can have on organizational effectiveness and personal well-being, it is not surprising that it remains an important construct in organizational research. Recent work has proposed a comprehensive framework for understanding the definitional components of conflict. This model reinforces the traditionally accepted differentiation between task and relationship conflict while also proposing affective, behavioral, and cognitive elements. Although this construct has been the center of empirical attention for decades, there are still many promising directions for future research.

CONFLICT MANAGEMENT

Conflict in organizations has received considerable attention in the business, psychology, and communication literatures. Nevertheless, a concise definition of conflict is lacking across studies and disciplines. In fact, researchers often provide definitions that differ from one study to another or fail to define conflict as it is measured in their studies. There is some agreement, however, that conflict takes place between two or more parties and constitutes a disagreement, an interference, and a negative emotional reaction. Two widely accepted sources of conflict are task conflict and relationship conflict. Furthermore, conflict can occur at the intrapersonal, interpersonal, intragroup, and intergroup levels.

Research on interpersonal conflict, also known as dyadic conflict, can be classified into one of two streams focusing on the occurrence of the conflict or its management. Conflict emergence studies explore the frequency or amount of conflict that respondents experience and its associated consequences. The second stream concentrates on the styles that employees use to manage interpersonal conflict at work, and this is the focus of this entry.

WHAT IS CONFLICT MANAGEMENT?

Conflict management differs from conflict resolution in that the latter is primarily focused on the termination or reduction of conflict. Resolution strategies such as mediation and arbitration often do not require interventions that result in changes to organizational processes or structures. Conflict management, on the other hand, emphasizes organizational learning to maximize the constructive aspects of conflict while minimizing its detrimental consequences. In fact, recent research in the business field suggests that a moderate amount of task conflict is functional and desirable. These studies also posit that relationship

conflict is deleterious to the work environment. For example, task conflict is associated with enhanced decision quality among top management, whereas relationship conflict is detrimental to decision quality. Therefore, an effective conflict management system is one in which employees adopt a conflict style that is appropriate for the situation while balancing the amount and type of conflict encountered.

Conflict management may be depicted as a process of conflict measurement and intervention development. In other words, a critical first step in conflict management is to assess the amount, source, level, and style of handling conflict. Although limited psychometrically sound measures exist to measure the amount of conflict perceived by employees, more options are available to measure styles of handling conflict situations. A comprehensive diagnosis is needed to formulate an organizational intervention. Such an intervention may require that employees be trained on when and how to use different styles of handling interpersonal conflict. Like any other training program, however, this type of process intervention is dependent on organizational support so that employees are able to apply newly learned skills when managing conflict on the job.

A second type of intervention emphasizes changing characteristics of the organization to help manage conflict. For example, the cause of conflict may be a poorly designed reward system, which results in personal rivalries among colleagues and a high number of relationship conflicts. In this case, a structural intervention would focus on designing a reward system that is perceived to be fair. Other structural interventions may focus on changing organizational procedures that cause conflict or structuring the organizational hierarchy in such a way that parties can appeal to a higher authority when they are unable to reach a decision.

CONFLICT MANAGEMENT STYLES

Individuals differ in their styles of handling conflicts. In fact, employees may resort to different styles of conflict management depending on the situation. The choice of style is influenced by a variety of factors, such as what has worked for the individual in the past, the style of their adversary, and norms surrounding the conflict situation. Several models of conflict styles have been proposed over time. For example, Morton Deutsch proposed a two-style model in which

individuals engage in a competitive or cooperative style. Others have posited a three-style model of conflict management that includes nonconfrontation, solution orientation, and control. Four-style models have also received attention. For example, the model of Dean G. Pruitt proposes four styles of conflict management: yielding, problem solving, inaction, and contending. However, a five-style model has received the most attention and empirical support; therefore, emphasis will be placed on M. Afzalur Rahim's five styles of conflict management.

Five Styles of Conflict Management

The five styles of conflict can be mapped onto a two-dimensional conceptualization that includes concern for self and concern for others. Other researchers, such as Kenneth W. Thomas, Robert R. Blake, and Jane S. Mouton, have also introduced similar conceptualizations. In essence, individuals range in their desire to satisfy their own concerns and those of other people. Based on where a person falls (high or low) on these two dimensions, he or she will use a different style of conflict management. The five styles are as follows:

1. **Avoiding:** An individual using an avoidant style displays low concern for self and others. Such an individual may deny the existence of conflict or be noncommittal in a conflict situation.
2. **Obliging:** An individual using an obliging style displays low concern for self and high concern for others. In essence, the individual chooses to sacrifice his or her concerns to accommodate the interests of others. This style is also known as yielding in other five-style models.
3. **Dominating:** A dominating style is one in which the individual shows a high degree of concern for self and low concern for others. This style may be characterized by assertive, competitive, and forcing behaviors.
4. **Integrating:** An individual who displays high concern for self and others engages in an integrating conflict management style. This style focuses on achieving a solution that maximizes the satisfaction of both parties and emphasizes problem solving. This style is also known as collaborative.
5. **Compromising:** This style represents a moderate degree of concern for self and others. In essence,

this style is likely to produce a solution in which both parties are willing to give up some of their interests.

These five styles can be further mapped onto a distributive or integrative dimension. The distributive dimension refers to gratification experienced by one of the parties, whereas the integrative dimension refers to gratification experienced by both of the parties. The avoidant and integrative styles of conflict management fall into the integrative dimension because neither or both parties are able to satisfy their interests, respectively. The distributive dimension comprises the obliging and dominating styles, in which satisfaction of concern for self is either low or high, respectively, thus allowing only the interests of one of the parties to be fulfilled. Although the compromising style results in some gains and some losses for both parties, Rahim posits that it can be thought of as the intersection of the integrative and distributive dimensions.

The effective use of the five conflict management styles depends on the characteristics of the conflict situation. For example, the integrative style may be most effective in resolving a specific conflict situation at Time 1, but it may not be the best style in a different situation at Time 2. Researchers have suggested guidelines for when each conflict style is most appropriate.

Specifically, the avoidant style is most strategic when there is a risk of violence, when the conflict issue is not important, or when it is unlikely that the conflict can be solved in a way that is self-benefiting. An obliging style is most appropriate when it is unlikely that one's interests will be satisfied. It is also effective when the opposing party has more power or believes that he or she is correct. This style is also appropriate in situations in which the outcome is inconsequential.

A dominating style is best used in situations in which a decision must be made quickly and the opposing party is uncooperative or unable to make a decision. This style is also effective in cases in which the dominating party is not concerned with risking the relationship and when the issue is important enough to impose one party's interests on the other party. However, when it is best to define a solution that is profitable for both parties, an integrating style is most appropriate. Such a style is suited to complex conflict situations in which problem solving requires that both parties engage in finding a solution and time is

available to do so. This style is also the best choice in situations in which one party cannot resolve the conflict alone. Finally, a compromising style is most effective when fulfilling all of a party's interests is not essential. It is also suitable in situations in which neither party is more powerful than the other and when the parties are willing to accept some losses in exchange for some gains. Compromise may be attempted when parties are not willing to engage in an integrating or problem-solving approach and a quick solution is necessary.

Studies have compared the five styles of handling conflict and attempted to make general conclusions about which styles work best. Overall, studies suggest that an integrating style is associated with outcomes of organizational importance such as commitment, performance, and satisfaction. The obliging and compromising styles correlate with positive outcomes, whereas the avoidant and dominating styles are associated with negative organizational outcomes. However, these findings should be interpreted with caution because the specific characteristics of the situation should not be overlooked in choosing a style.

Dispositional Influences on Conflict Management Style

Not only are situational characteristics influential in the selection of a conflict management style; dispositional factors also play an important role in style choice. Different personality dimensions, such as need for affiliation, self-monitoring, and the Big Five, have been investigated in relation to the five styles. These studies report that individuals low on need for affiliation prefer a dominating style, whereas those high on need for affiliation tend to use an obliging style. Compromising and integrating styles are more likely to be used by high self-monitors. Furthermore, an integrating style is correlated with conscientiousness, openness to experience, agreeableness, and extraversion such that participants who are higher in these traits are more likely to use this particular style. Individuals who are high on agreeableness and neuroticism are more likely to use an avoidant style, whereas those who are high on extraversion preferred a dominating style. The evidence thus suggests that individuals may have tendencies to use one style over another. However, whether the style is congruent with situational characteristics determines the success of the conflict management efforts.

CONCLUSION

Conflict is inevitable in organizational life. However, through effective conflict management, organizations can minimize the negative sources of conflict while promoting functional amounts of task conflict. The conflict management process begins with a thorough assessment of the amount of conflict and the styles of handling conflict used by organizational members. This information is necessary in the design of an intervention that targets either the structural characteristics of the organization, the processes that are in place, or both. A critical component of such interventions is teaching employees about the different styles of conflict management that are available to them and the situations in which each is most appropriately used. Although research suggests that some styles of conflict management are more effective than others, it is important to keep in mind that both situational and dispositional factors play a role in their effective use and selection.

CONSTRUCT

A construct, also known as a hypothetical construct or a psychological construct, is a scientific tool used to facilitate understanding of human behavior. All sciences are built on systems of constructs and their

interrelations. The natural sciences use constructs such as gravity, temperature, phylogenetic dominance, tectonic pressure, and global warming. Likewise, the behavioral sciences use constructs such as conscientiousness, intelligence, political power, self-esteem, and group culture.

The simplest way to think about a psychological construct is to consider it a label for a cluster or domain of covarying behaviors. For example, if we observe someone sitting in a classroom before an examination biting his or her nails, fidgeting, lightly perspiring, and looking somewhat alarmed, we might say that he or she is experiencing test anxiety. In this case, test anxiety is a label for the covariation that we attribute to these behavioral observations. Some scientists extend this conceptualization and suggest that test anxiety is an underlying cause of the behaviors that we observed. Used in this way, a construct is a hypothesized cause for the behavioral covariations that we observe.

A construct derives its name from the fact that it is a *mental construction*. In other words, science is built on the general process of (a) observing natural phenomena, (b) inferring the common features of those observations, and (c) constructing a label for the observed commonality or the underlying cause of the commonality. Any given construct derives its scientific value from the shared meaning it represents for different people. That is, if a construct is clearly articulated and the phenomena it encompasses are clearly defined so that different people think similarly about it, then it becomes a useful conceptual tool that facilitates understanding and communication. Once defined, constructs become objects of conceptual scrutiny in their own right. In other words, psychologists hypothesize both (a) whether certain behaviors will covary and (b) whether the clusters of covarying behaviors (i.e., constructs) tend to covary in meaningful ways with other constructs.

Constructs summarize behavioral domains and allow extrapolations to unobserved behaviors. For example, after telling your friend that a classmate had test anxiety, your friend might assume the occurrence of or attribute many more behaviors to the classmate than you actually observed (e.g., skin rash, grinding teeth, sweaty hands, or crying). This extrapolation underlies much of the psychologist's predictive power. If certain behaviors can be observed, then other unobserved behaviors can be predicted to occur in the future. Of course, the accuracy of these

predictions depends largely on the quality of the conceptual and psychometric foundations of the construct in question (i.e., construct validity).

Constructs are hypothetical. They exist as concepts but not as tangible entities. Yet some constructs become so familiar and ingrained in common use that most people assume their manifest existence. To illustrate this, bet someone that he or she cannot show you gravity. The person will probably take you up on the bet, and then he or she might pick up a pencil or some car keys and drop them on the floor and look at you smugly, as if to say, "There, I showed you gravity." You can respond by authoritatively saying that you have been shown a falling pencil or keys but not gravity. Gravity is a label for the hypothetical cause of the falling pencil and keys, but it is not the observable events. The same scenario can be built around any psychological construct—for example, extraversion, quantitative ability, and finger dexterity. We never see extraversion, except in our mind's eye. We see extraverted behaviors, and we summarize these by evoking a construct label and inferring that the person who exhibited those behaviors is extraverted to some degree or another.

Constructs are the building blocks of scientific theories. Psychologists who are interested in studying and understanding human behavior are interested in identifying behavioral regularities and their causes. Constructs help research and applied psychologists to summarize the complex array of observed behaviors, emotions, and thoughts that people produce in their day-to-day activities. Research may focus on identifying and clarifying construct boundaries, or determining which constructs relate to other constructs, as a basis for theorizing functional relationships between systems of constructs. Applied psychologists use constructs to make decisions about how to treat people with certain psychological disorders or whom to select, train, and promote for certain jobs or careers in organizations.

The discussion thus far has focused on psychological constructs as naturally occurring domains of behavior, and this is the most common way to conceptualize constructs. However, organizations also create domains of covarying behaviors. This is how different jobs and tasks are defined. These *performance* domains are constructs, but in a conceptually different sense than we have discussed. Performance domains are conceptually distinct from psychological constructs in that rather than natural covariation,

behavioral covariation is induced by organizational designers and employment specialists collaborating to translate broad organizational objectives into domains of valued behaviors and outcomes. Viewed either way, constructs are useful tools for simplifying our understanding of human behavior.

CONTENT CODING

In organizational surveys, also often referred to as employee attitude surveys, data are gathered in two general forms, quantitative and qualitative. Quantitative approaches typically involve a statement (e.g., “Processes and procedures allow me to effectively meet my customers’ needs”) followed by a scale of response options (e.g., “strongly agree . . . strongly disagree”). This can be called a quantitative approach to measuring attitudes because the resulting data will be in the form of numbers.

By contrast, a qualitative approach allows free-form text to be entered by the person taking the survey. These are often referred to as open-ended questions or write-in questions, a term born in the days when surveys were typically conducted using paper and pencil and employees were given an opportunity to provide comments in their own handwriting. Today, many, if not most, surveys are administered using a computer, and comments are actually typed in.

The following are some typical examples of write-in questions:

- Please provide any comments you have on what it feels like to work here at Company X.
- Please provide any suggestions you have about how Company X could better enable you to balance your work and personal/family life.
- Do you have any additional comments or suggestions?

USES

The clarification of issues that are on the minds of employees, in their own words, is a powerful benefit of gathering comments in a survey. Although quantitative data can provide precision, trending, and easy comparisons to benchmarks, write-in comments add richness by bringing abstract issues to life through specific examples, new ideas, and suggestions for improvement.

Gathering comments also allows the researcher to gain insight into a new issue, one in which the important elements are only partially known. For example, a survey may contain a question about the most important characteristics of an employee benefits program. One might have some good hunches about benefits such as flexibility, health coverage, and dependent care. However, an open-ended question asking employees to describe what they would like to see in “the perfect benefits package” would provide a much more complete list of issues. Follow-up questions in later surveys—with a more tested list of issues—could then be used in a quantitative approach to monitor the effectiveness of the benefits programs.

TECHNIQUES

Content coding of open-ended data is a process of reading through a set of comments or a subset of comments and describing themes that tie together many individual comments. These themes are analogous to the principal components of a factor analysis. Common themes in open-ended data depend on the questions being asked, but they will often include elements that are common to a workplace climate survey: compensation, management, jobs, workload, work-life balance, and business performance.

Some researchers ask the employees who are taking the survey to help code their comments while they

are taking the survey. For example, a write-in question could be preceded by a list of topics that employees choose from to describe the theme of their comments. It is also possible to ask specifically whether the comment is generally positive or negative. This can help provide an initial structure to work with in developing themes.

One approach to developing themes is to keep a tally of issues mentioned as comments are read. Because of the ambiguity of the meanings of words and phrases, it is important to take a systematic approach to developing categories and coding comments. One simple approach is to have two raters set up initial categories based on their reading of the same portion of an open-ended data set. Through discussion of any differences in the taxonomies, a more stable and useful set of categories and coding rules can be derived for use in coding the rest of the comments. Reliability can be assessed through agreement among different raters on assigning themes to comments. If agreement between raters is low (e.g., less than 90%), then the researchers should review and refine their category list and coding rules and recode the comments until adequate reliability is achieved.

Because of the large size of some qualitative data sets, the task of reading through open-ended comments can be overwhelming. One approach to handling the volume is to sample a portion of the comments. If there are 2,000 comments, for example, reading through 400 of them (or every fifth comment) will usually give a good feel for the entire set of comments. This is similar to the notion of sampling as it is applied to quantitative results. Although the concept of a margin of sampling error makes little sense when applied to open-ended comments, redundancy will begin to appear after a couple hundred comments. By the time a reader reaches 400, few completely new suggestions or ideas will emerge.

Computer technology continues to evolve, and it offers some intriguing new techniques for deriving themes and understanding open-ended data. Researchers can use content-coding software tools, also called text-mining tools, to uncover themes within their qualitative data set. At a minimum, this provides an initial structure to use when reading through comments.

Content-coding tools require researchers to define certain terms and phrases, which the computer then uses to evaluate similarity across comments. For example, the terms *CEO*, *president*, *chairperson*, and even the proper name of a person, such as *Jane Doe*,

may all have the same meaning in a given organization. Similarly, the terms *compensation*, *pay*, *benefits*, and *money* may be defined as belonging to the same category. With patience and an iterative technique for defining the right terms and phrases in a given survey project, text-mining software can help researchers define themes in an open-ended qualitative database.

This iterative technique also becomes the process whereby the researcher learns about and defines the themes. The results should be reviewed and the dictionary refined multiple times to produce the most useful data set. Elements that prove tricky to define include evaluations of goodness. For example, a comment that reads *not very good* needs to be defined as a negative comment. Sarcasm and irony can prove especially difficult for a computer to classify properly.

Content-coding software produces a kind of map representing the comments. Often this map will be structured visually, with large circles representing themes that contain many comments and smaller circles representing themes that are less commonly mentioned. These thematic circles can be connected by lines indicating their similarity or redundancy in content with other themes. The researcher now has a starting point for reading through the comments.

CAUTIONS AND RECOMMENDATIONS

Exclusive reliance on open-ended comments is not recommended. Although write-in comments provide a richness of perspective that is not available with quantitative data, research has found that comments provide a somewhat more negative view of the state of a workplace climate than quantitative results. This is because people who are dissatisfied tend to use write-in comment opportunities more often than satisfied employees. Similarly, those who are dissatisfied with an issue will often provide more lengthy comments than those who are satisfied. Therefore, it is important to look to both quantitative and qualitative data—in addition to the surrounding context—to paint an accurate representation of a workplace climate.

Some researchers argue that open-ended qualitative data usually overlap and therefore are redundant with quantitative results. This calls into question whether it is worth the effort to include open-ended comment opportunities in an employee survey.

In the end, employees want to speak their minds about the workplace. Employers can gain insight into the workplace climate by using open-ended data

collection. Sampling and content coding tools can help researchers and organizational leaders gain the rich insights provided by open-ended comments without being overwhelmed by them. Another simple method of keeping write-in comments at a manageable level is to restrict the length allowed (for example, to 10 or 20 lines of text).

Regardless of methods used and the questions asked, it is critical for the integrity of the survey process to be clear about whether the survey is anonymous, who will see the results, and how the results will be used. With regard to open-ended comments, it should be clear who will see the comments and whether they will be edited (e.g., to remove proper names or foul language). Transparency about the purpose and methods used in a survey project or program will go a long way toward protecting the validity and utility of employee attitude measurements.

CONTEXTUAL PERFORMANCE/ PROSOCIAL BEHAVIOR/ ORGANIZATIONAL CITIZENSHIP BEHAVIOR

Although the origin of what is called *organizational citizenship behavior*, *contextual performance*, or *prosocial organizational behavior* can be traced back to classic management and organizational science

treatises, serious theoretical and empirical research in the area did not begin until the late 1970s. Researchers Dennis Organ, Walter Borman, Stephen Motowidlo, Phillip Podsakoff, and Scott MacKenzie have been instrumental in the development and popularization of this construct.

The relevance of organizational citizenship behavior rests primarily on the persuasive contention that job performance should encompass not only behavior that contributes to the technical core of the organization, referred to here *task performance*, but also behavior that contributes to organizational performance by shaping the organization's social and psychological environment, known as *organizational citizenship behavior*. The former category includes duties that are listed in the employee's job description (e.g., an industrial truck or tractor operator operates a machine that transports, lifts, stacks, loads, packages, or cuts products), whereas the latter category includes behaviors such as volunteering for tasks that are not required, helping other employees with their work, and praising the organization to outsiders.

Relative to task performance, employees perceive that organizational citizenship behavior is required by the job less frequently, and supervisors and other organizational authorities recognize and reward its expression less frequently. Thus, employees are believed to have more latitude in performing (or not performing) organizational citizenship behavior than they have in task performance. Consequently, Organ proposed a variant of the *happy/productive worker hypothesis*: In his version, job satisfaction is posited to predict organizational citizenship behavior rather than (task) performance. Borman and Motowidlo proposed that organizational citizenship behavior (which they termed *contextual performance*) should be better predicted by personality, whereas task performance should be better predicted by general mental ability (i.e., intelligence).

These predictions are consistent with the idea of *situational strength*. To the extent they are mentally and physically able to do so, individuals will exhibit behavior (i.e., task performance) that is prescribed by the situation. However, the extent to which individuals exhibit behavior (i.e., organizational citizenship behavior) that is not explicitly prescribed by the situation depends on volition.

Later, we will examine the extent to which these early predictions have been borne out by empirical research. First, though, it is necessary to examine organizational citizenship behavior in more detail.

STRUCTURE OF ORGANIZATIONAL CITIZENSHIP BEHAVIOR

Should organizational citizenship behavior be treated as a cohesive entity, or are there different types or facets of citizenship that are important in their own right? According to Organ's taxonomy, there are five facets of citizenship: (a) altruism, helping others; (b) conscientiousness, or engaging in role-required behavior, but doing so beyond minimum required levels; (c) sportsmanship, or refraining from complaining about trivial matters; (d) courtesy, or providing others with advance notice, reminders, and information; and (e) civic virtue, or contributing in a responsible fashion to the corporate governance of the organization. Borman and Motowidlo, in contrast, proposed the following five types of citizenship: (a) persisting with enthusiasm and extra effort as necessary to complete one's own task activities successfully; (b) volunteering to carry out task activities that are not formally part of one's own job; (c) helping and cooperating with others; (d) following organizational rules and procedures; and (e) endorsing, supporting, and defending organizational objectives.

Other taxonomies have been proved moot. Yet the most consistent distinction is between citizenship behavior that is directed toward the organization and behavior that is directed toward other employees in the organization. Behavior that is directed toward the organization includes actions such as displaying loyalty to the organization and following informal rules designed to maintain order, whereas behavior that is directed toward other employees includes being considerate to others and helping them with their work.

In general, theoretical attempts to distinguish between facets or types of organizational citizenship behavior have not been overly convincing. Perhaps more crucially, findings from meta-analyses indicate that the facets are strongly interrelated and that their relationships with a variety of other constructs are relatively similar in strength. In other words, the case for disaggregating organizational citizenship behavior into more specific facets has not yet been made. It is unsurprising, therefore, that many researchers continue to use overall measures rather than facet measures of the construct.

The construct definition of organizational citizenship behavior would be incomplete without a discussion of its relationships with other job-related constructs. Hence, we turn to this issue next.

RELATIONSHIPS WITH OTHER CONSTRUCTS

The relationships of organizational citizenship behavior with other constructs are best assessed by separately considering relationships with (a) constructs concerned with appraisals of and attitudes toward the job; (b) dispositional constructs; and (c) other employee job performance facets, global employee job performance, and organizational performance.

Relationship With Job-Related Appraisals and Attitudes

Social exchange theory, the theory of psychological contracts, and the norm of reciprocity have been used to explain the relationship between organizational citizenship behavior and organizational justice, leader supportiveness, job satisfaction, and organizational commitment. These theories predict that employees respond to satisfying working conditions, supportive leaders, and fair workplace processes, outcomes, and interactions by engaging in organizational citizenship behavior and exhibiting organizational commitment. Thus, organizational justice, leader supportiveness, and job satisfaction are conceptualized as antecedents of organizational citizenship behavior, whereas organizational commitment is conceptualized as neither an antecedent nor a consequence. In contrast, other theoretical formulations conceive of organizational commitment as an antecedent. Because the vast majority of studies have been cross-sectional in design, however, we are unable to clearly ascertain temporal precedence.

Of the predictors just mentioned, the most research attention has focused on job satisfaction and organizational justice. Yet meta-analyses (quantitative reviews of existing research studies) indicate that job satisfaction, organizational justice, leader supportiveness, and organizational commitment are all weak to moderate predictors of organizational citizenship behavior and, consequently, none of them stands out as being a much better predictor than the others.

Relationship With Dispositional Constructs

Appraisals of and attitudes toward the job are largely (though not completely) dependent on conditions and experiences on the job. Thus, their study is consistent with a philosophy in which certain workplace situations are more conducive to organizational

citizenship behavior than others. In contrast, the quest for dispositional antecedents is consistent with a philosophy in which certain types of employees (the “good soldiers”) are more apt to perform organizational citizenship behavior than others. Armed with knowledge of dispositional predictors, researchers could design selection tests to screen out applicants who are less likely to engage in citizenship.

Meta-analyses conclude that employees who are more conscientious—that is, those who exhibit greater industriousness, orderliness, and self-control—engage in more organizational citizenship behavior than those who are unconscientious. Yet conscientiousness is best characterized as a weak to moderate predictor of citizenship. It thus predicts citizenship about as well as the appraisal and attitudinal constructs discussed previously.

Other consistently examined dispositional contenders, such as agreeableness and affectivity (emotionality), appear to be weak predictors of citizenship. Apart from conscientiousness, therefore, the search for dispositional predictors of organizational citizenship behavior has proved disappointing.

Meta-analyses have produced another interesting finding. Recall that organizational citizenship behavior (or contextual performance) was originally touted as a construct that, unlike task performance, is strongly influenced by job satisfaction and personality. Yet the findings indicate that neither appraisals and attitudes nor dispositions predict organizational citizenship behavior to an appreciably greater extent than they predict traditionally conceptualized performance. This may be because some traditional conceptualizations, such as ratings or judgments of employee performance, do not represent only task performance: As we will see, they are also infused with organizational citizenship behavior.

Relationship With Performance Constructs

Organizational citizenship behavior has been differentiated conceptually from task performance, but what is the strength of the empirical relationship between these constructs? Results indicate that employees who are good task performers generally engage in more organizational citizenship behavior. There is one important caveat, however: The relationship appears to be strong only when task performance

and citizenship are both measured using ratings and judgments by the same person. When task performance is measured objectively (e.g., using measures of quantity or quality of work that require no judgment) or when the person who is rating task performance is not the same person who is rating citizenship, the relationship between the two constructs is best construed as moderate.

Apart from task performance and organizational citizenship behavior, another aspect of overall employee job performance is counterproductive work behavior. This refers to intentional employee behavior that is harmful to the legitimate interests of an organization, and it encompasses behavior ranging from lateness, lack of effort, and spreading malicious rumors to more severe actions such as theft, vandalism, and drug and alcohol abuse on the job. In a sense, the definitions of organizational citizenship behavior and counterproductive work behavior set them up to be opposites. But the two constructs have been linked, albeit in opposite directions, to the same set of dispositional and appraisal or attitude constructs. Yet meta-analysis has demonstrated that the (negative) relationship between the constructs is only moderate in strength. In addition, relationships with antecedents are generally stronger, sometimes substantially so, for counterproductive work behavior than for organizational citizenship behavior.

Which of these components of employee job performance is most important to supervisors? Certain studies have assessed how supervisors weigh employees’ task performance and organizational citizenship behavior, and, in general, they conclude that the latter is at least as important as the former in determining judgments and ratings of overall job performance. Only one study has considered counterproductive work behavior as well; intriguingly, its results indicate that supervisors consider citizenship less important than counterproductive work behavior.

Finally, the extent to which organizational citizenship behavior improves the functioning or performance of the organization (as a whole) has been scrutinized. Results are generally supportive, regardless of whether the latter is measured using quantity, quality, financial, or customer service (satisfaction and complaints) indexes. As several researchers have commented, however, theory on the mechanisms by which employee citizenship behavior influences organizational performance is scant.

RECENT DIRECTIONS

Thus far, much attention has been paid to the person who is enacting the organizational citizenship behavior. With regard to predicting interpersonal citizenship behavior (i.e., behavior directed toward other employees rather than toward the organization), however, researchers are awakening to the potential of studying the *relationship* between the actor and the recipient(s) of the behavior. It has been argued that the extent to which person X helps person Y depends on much more than merely person X's predilections and his or her reactions to the work situation. Specifically, it is important to consider relational features such as the positivity or negativity of the relationship between person X and person Y, how often and for how long they have interacted, whether they are linked by more than one type of relationship (e.g., coworker, friend, and neighbor), and the extent to which they share common friends.

At the same time, important advances are being made with regard to the person who is enacting organizational citizenship behavior. To date, most research of a situational bent has employed relatively stable job-related appraisals and attitudes as predictors of citizenship. In other words, reactions to situations—hence organizational citizenship behavior itself—have been treated, in effect, as differences between individuals. Yet is it not possible for a given individual to display levels of organizational citizenship behavior that fluctuate rapidly over time? An influential contemporary theory, *affective events theory*, contends this may be the case. At the risk of oversimplification in the service of brevity, the theory suggests the following:

- Mood and emotions on the job fluctuate rapidly over time and can be distinguished from more stable cognitions or evaluations about the job.
- Whereas other types of work behavior are influenced primarily by job-related cognitions or evaluations, organizational citizenship behavior is influenced primarily by mood and emotions at work.

With regard to organizational citizenship behavior, a growing body of empirical research now supports this theory. Results suggest that a substantial proportion of the variation in organizational citizenship behavior occurs within an individual over time (rather than because of differences between people) and that mood and emotions predict these dynamic aspects of citizenship better than do commonly used dispositional and appraisal or attitudinal predictors.

Finally, several authors—but most notably, Mark Bolino and colleagues—have begun to question key assumptions in the research literature. For example, one common assumption is that employees' motives for engaging in citizenship behavior are not self-serving. This, however, excludes motives such as impression management, making amends for previous or anticipated (future) counterproductive behavior, and avoiding normal responsibilities (i.e., task performance).

It has also been assumed that organizational citizenship behavior improves organizational functioning. This assumption is so centrally held that it is part of the very definition of organizational citizenship behavior. Despite research showing that citizenship behavior tends to lead to better organizational performance, however, we might question whether this is always (or must necessarily be) the case. Organizational performance may not improve—and may even be affected adversely—if organizational citizenship behavior takes place instead of, rather than in addition to, task performance. Additionally, in some instances, the organizational bottom line (and perhaps even employee satisfaction) may be better served by hiring additional employees to reduce the need for existing employees to engage in organizational citizenship behavior.

A third assumption is that citizenship goes beyond behavior that is required and therefore may not be noticed or rewarded to the same extent as task performance. Yet evidence indicates that employees do perceive citizenship as being required to some extent, and supervisory performance evaluations are nontrivially influenced by employees' citizenship behavior. In response to these concerns, Organ recently agreed that the definition of organizational citizenship behavior should sidestep the issue of whether such behavior is required. The question that remains, though, is whether there are situations (or jobs) in which organizational citizenship behavior is perceived to be required as much as, if not more than, task performance.

The directions charted here require new methodological and statistical techniques and, more generally, new ways of thinking about the world. Further redefinition of the construct of citizenship may also be required. These directions are not easy to navigate, yet they present exciting opportunities to build on the solid foundation created by extant research on organizational citizenship behavior.

CONTROL THEORY

Careful observers of humans and other organisms noticed long ago that certain variables that should vary as environmental conditions change actually do not vary much within the organism. For example, store shelves remain stocked despite customers buying products. Control theory arose as one explanation for the mechanism that keeps variables stable.

Industrial and organizational psychologists find the explanation provided by control theory very useful for conceptualizing and understanding a great number of work-related phenomena.

The specific mechanism described by control theorists contains three parts:

1. A function that translates the state of some variable (e.g., the state of stock on shelves) into a perception or signal that can be compared with a desired perception or reference signal (e.g., fully stocked) represented within the organism
2. A second function that does the actual comparison, subtracting one signal from the other
3. Positive differences from the second function, called the *error signal*, that are then passed to the last function, which translates the error signal into actions (e.g., restocking shelves) on the variable in question

If the control mechanism is operating properly, the actions bring the variable in line with the desired perception of that variable. That is, the actions reduce the discrepancy (i.e., error) between the perception of the variable and the desired state of the variable. As a result, the variable remains near the desired level despite outside influences, called *disturbances*, on the variable.

Anyone who has studied psychology is likely to be familiar with this mechanism as it applies to physiological variables such as hunger and thirst control. In this context, the term *homeostasis* is generally used to refer to the sameness (*homeo*) in state (*stasis*) of a variable over time. Others might be familiar with the concept through engineering circles. For example, it is the mechanism underlying temperature control systems in your home, as well as the systems that make “smart” appliances work, such as cruise control in automobiles or the popcorn setting on microwave ovens. In this context, one might hear the term *cybernetic*—a term coined by the mathematician Norbert Wiener, who described the mechanism formally with mathematics—or *negative feedback loop* (because the process reduces the error signal). Within the context of industrial and organizational psychology, all of these terms have been used, but the mechanism most often operates within what we call *theories of self-regulation*.

In psychological renditions of control theory, the basic control system (defined by the three functions

described previously) is conceptualized within hierarchies of systems, and it is from this configuration that some of the more interesting phenomena emerge. Specifically, three additional elements are described in these psychological versions:

1. The “actions” of higher-level control systems determine the reference values for lower-level systems, and the perceptions from lower-level control systems feed into higher-level control systems, allowing them to create more abstract and complex perceptions.
2. The reference signals can be diverted back to the sending system as a means of anticipating or estimating the effects of the system’s actions. Usually this is called a feed-forward process; it is control theory’s conceptualization of human thinking.
3. Some control systems monitor the operation of other systems and act on those systems by changing the three kinds of core functions described earlier. This is control theory’s conceptualization of learning.

With these additional elements, control theorists hope to understand a wide range of phenomena in psychology. Likewise, within the field of industrial and organizational psychology, control theory and its variants have been used to address many issues. For example, human factors researchers are interested in the processes by which humans control aspects of their immediate physical environment. Control theory has been used as a significant explanatory tool in that domain. In addition, control theory has been applied to understanding stress and affective processes within work domains. However, control theory’s most prominent presence in industrial and organizational psychology relates to motivation and goal-striving behavior within organizations.

CONTROL THEORY AS A THEORY OF MOTIVATION

To understand control theory’s relevance to motivation, one need only substitute the control theory notion of *internally represented desired state* (i.e., reference signal) with the term *goal*. Thus, control theory provides an explanation of how individuals achieve and maintain their goals, whether individuals bring these goals with them or acquire them from the work

context. Indeed, another situation in which control theories are used is to describe when managers and supervisors are likely to communicate goals and desired behavioral patterns to their subordinate employees.

Elsewhere in this encyclopedia, you can read about the relevance of goals to understanding human motivation and how goals have practical implications for performance and other organizationally relevant outcomes (e.g., absenteeism). The literature on goals—most developed without the benefit of control theory—has demonstrated robust, positive effects on motivation and performance for interventions based on goals and their properties. This has led some researchers to seek explanations for these goal effects (i.e., understand why goals have the effects they do) and to understanding how individuals coordinate the pursuit and maintenance of multiple goals more or less simultaneously. Researchers argue these understandings may provide better or unique applications that have not yet been considered, and control theory is considered a major source for developing these understandings.

Alongside goals, another concept that has received a great deal of attention is *feedback*, a complex concept. In industrial and organizational psychology, feedback generally refers to the information that supervisors or others give employees regarding their performance or actions. This kind of feedback has long been considered important in organizational contexts, and it is believed that interventions that increase feedback boost performance. Yet in this case, the empirical evidence is mixed, though generally positive (i.e., feedback interventions generally improve performance). Control theory has been used here as well as a vehicle for understanding the processes by which feedback has its effects (both positive and negative). Meanwhile, feedback is sometimes actively sought by employees; control theory is used to understand why and when that happens.

Across all applications, the concept that has received the most attention is the notion that information (i.e., feedback) may indicate discrepancies between perceptions and goals. These discrepancies, in turn, drive behaviors and the allocation of resources to reduce the discrepancies. For example, a perception of uncertainty regarding one’s performance is presumably responsible for feedback-seeking behavior among individuals who desire certainty. The information received from that feedback-seeking episode

might, if it creates discrepancies with other work goals, motivate increased work.

However, given the complexity of work contexts, many times behaviors and the allocation process result in conflicts, such that individuals may behave in ways that take them away from or steal resources needed for other goals. Thus, a person's attention might be drawn to one goal in his or her hierarchy, although it is needed in another. If both goals are required for effective performance, it is in the interest of the employee and the employers to figure out how to balance or regulate competing demands for resources. Indeed, at this point, researchers are interested in simply understanding how control systems regulate (i.e., self-regulation). Worrying about how to optimize this regulation for specific outcomes requires a more thorough understanding of the processes involved.

CONTROVERSIES RELATED TO CONTROL THEORY

Although control theory has many adherents and variants within industrial and organizational psychology, it also has some strong opponents. One source of opposition may stem from its success. That is, the multiple uses and phenomena to which control theory has been applied have produced so many variations that critics complain it is difficult to know what control theory is and what it is not. Moreover, these variations often incorporate ideas and concepts used by other theories, leading critics to wonder whether control theory makes any unique contribution to the theoretical landscape. For example, goals were in psychologists' lexicon before control theory was brought to the field; thus, some argue it is not useful to mix psychological constructs with the control theory labels commonly used by engineers. Control theorists counter that the theory's unique contribution is to explain why goals have the effects they do, not necessarily what the effects are.

Recently, control theorists have concerned themselves with the concept of self-efficacy, a central construct in social cognitive theory. Self-efficacy, or the belief in one's capacity to perform or act at a given level, is not a construct that is described within any version of control theory. However, self-efficacy measures capture the results of the feed-forward process described within control theory. Moreover, the results of the feed-forward process, as it is used within

control systems, lead to similar—but not identical—predictions that social cognitive theory describes for self-efficacy. Yet the points of divergence are what theoreticians find most interesting, and they may be practically relevant as well. In this case, social cognitive theory predicts strong positive effects. In contrast, control theory predicts weak negative effects for self-efficacy on motivation and performance during goal striving when goals do not change and when feedback is ambiguous. Recent research supports control theory's predictions, which other researchers are now seeking to verify.

Control theory has also been criticized for its complexity. Control theory is a dynamic theory of processes. Most theories in industrial and organizational psychology describe the relationships between variables, generally across individuals rather than across time. Variables that describe relationships across time do not specify the processes by which the relationships emerge. Dynamic process theories explain why factors covary (or don't when it seems they should) over time. This makes control theory a very different kind of industrial and organizational theory. Indeed, this difference may be one of the main reasons it is appealing to so many researchers (i.e., it can be used to explain phenomena that other theories are not in a position to explain). Yet it is also difficult to reconcile with how one compares, contrasts, and tests typical theories in industrial and organizational psychology. Moreover, evidence has emerged that humans have difficulty predicting dynamic (i.e., changing) phenomena. Thus, trying to mentally simulate (i.e., think through) a dynamic theory's predictions about dynamic phenomena may be difficult—all the more reason for such a theory, say its proponents.

The preceding paragraph implied that the complexity of control theory arises from the limitation of human minds, particularly those without much experience thinking about phenomena dynamically. However, it seems that by most criteria, control theory models become extremely complex as the number of control systems used to explain a particular phenomenon increases. Indeed, control theorists, presumably facile at thinking dynamically, either describe relatively simple models (single or only a few control systems) or render the models mathematically (i.e., computational models) that can be simulated. The latter approach is likely necessary because the control theory explanation is too complex to think through. One needs the computation tools of simulations to

follow the implications of the control systems described. This is what engineers do, and psychologists are just beginning to use this process (especially in human factors research). It remains to be seen how useful the simulation tool will be to researchers examining motivation or to those wishing to apply control theory to specific organizational problems.

Control theory has a long history outside psychology. Many think it can have a long and fruitful history within the field of industrial and organizational psychology as well. How this conflict will play out in the field, only time will tell. If only we had a theory.

CORE SELF-EVALUATIONS

The term *core self-evaluations* refers to fundamental, global evaluations that individuals make about their worth as individuals, including whether they have the capability to handle the tasks and challenges they face in life and the extent to which they feel in control of

their lives. When faced with a problem or challenge, individuals with high core self-evaluations believe, “I can handle this problem.” Individuals’ tendencies to evaluate themselves negatively or positively may affect their evaluations of others and the world in general.

STRUCTURE AND MEASUREMENT OF CORE SELF-EVALUATIONS

Core self-evaluation is a broad personality trait that includes shared elements of some of the most frequently studied personality traits, including self-esteem, locus of control, and neuroticism. Although researchers have spent decades studying these individual traits (e.g., self-esteem, neuroticism), only recently have researchers begun to recognize the commonalities among them. Recent research indicates that four core traits—neuroticism (reverse scored), locus of control, generalized self-efficacy, and self-esteem—are highly related to one another. Individuals who score high in one of these traits tend to score high on all of them, leading researchers to believe that individual traits may all be linked to a common source or core, labeled core self-evaluations.

Although it is clear that strong associations between these traits exist, research to date is not clear about the nature of this association. It may be that core self-evaluations are the underlying cause of traits such as self-esteem and neuroticism. If this is the case, individuals vary in the extent to which their broad, fundamental evaluations of themselves are positive or negative, and these evaluations, in turn, influence their feelings of worth and value (self-esteem), control (locus of control), confidence (self-efficacy), and general emotional stability (neuroticism). According to this approach, each of the individual traits serves as an indicator of individuals’ core evaluations of themselves, which are not directly observable.

It is also possible, however, that the four core traits are linked to each other in a hierarchical manner. For example, it may be that self-esteem is the cause of the other traits: Individuals who have a low sense of self-worth (self-esteem) may tend to experience more sadness and anxiety (neuroticism) and have less confidence that they are capable of handling the challenges they face (self-efficacy) because they doubt their value.

The nature of the associations among the four core traits and the broader core self-evaluations concept,

especially their causal associations, remains unresolved. Researchers have attempted to sort out the causal associations between evaluative self-reported traits such as self-esteem and neuroticism using factor analyses; however, such approaches are open to multiple interpretations and preclude definitive conclusions. In the future, our understanding of these traits may be aided by the biological, brain, and genetic research that is currently under way in the field of neuroscience.

There are two approaches to the measurement of core self-evaluations. One is to use existing measures of the four traits. In this approach, core self-evaluations can be assessed by either (a) averaging the scores of the four traits, which assumes that the specific elements of each trait represent the underlying core self-evaluation, or (b) using factor analysis to extract the commonalities between the traits, which assumes that only the commonalities between the four core traits represent core self-evaluations. A second approach is to measure individuals' fundamental assessments of themselves and their capabilities directly. To this end, a short, comprehensive measure of core self-evaluations has been developed.

Emerging research suggests that core self-evaluations explain differences between individuals that are not captured by existing broad personality taxonomies, such as the Big Five. Although associations between core self-evaluations and the Big Five traits are to be expected (neuroticism is one of the four core traits), the Big Five traits cannot explain all of the differences between individuals in core self-evaluations. Furthermore, core self-evaluations have been shown to add incremental predictive validity to the Big Five traits in explaining important work and life outcomes, such as job and life satisfaction.

CORE SELF-EVALUATIONS AND WORK

Regardless of how core self-evaluations are measured, it is clear that this trait is linked to important aspects of work. The concept of core self-evaluations was developed to explain individual differences in workers' satisfaction with their jobs; however, it has also been linked to work motivation and job performance.

Early research on core self-evaluations showed that individuals who evaluate themselves positively also tend to be satisfied with their jobs. This appears to be true for several reasons. First, because individuals who are high in core self-evaluations tend to see

others and their work in a positive light, they may simply take a more optimistic view toward their jobs as well. Second, research indicates that employees with high core self-evaluations actually choose and attain better, more enriched jobs. When given a choice, individuals high in core self-evaluations tend to choose jobs that are more complex. They also may attain more enriched jobs over time because they have the confidence to try new things and are more willing to take on challenging assignments. Third, individuals with high core self-evaluations report setting job goals that are important to them. Recent empirical research shows that individuals with high core self-evaluations set goals that are more intrinsically interesting to them and represent their own values; they rate their work goals as more important. Perhaps for this reason, they are also more likely than individuals with low core self-evaluations to achieve their work goals, leading them to be more satisfied with their jobs.

In summary, individuals high in core self-evaluations tend to be happier with their jobs, partly because of their global positive evaluations but also because they attain more challenging and interesting jobs and are more likely to achieve important work goals than individuals low in core self-evaluations.

Core self-evaluations are also positively associated with ratings of job performance. To understand the link between core self-evaluations and job performance, several motivational mechanisms have been considered, including goal setting and expectancy motivation. Individuals with high core self-evaluations report setting goals that are more intrinsically interesting and important to them. They also set higher goals, are more committed to their goals, and engage in more goal-directed activities at work than do individuals with low core self-evaluations. Furthermore, because they evaluate themselves and their competence highly, they may be more likely to persist in the face of failure and attribute failure to external, temporary causes. Thus, they are likely to achieve higher levels of performance by setting high goals and persisting in goal-directed activities in the face of obstacles. In this regard, core self-evaluations may be an ability factor in some jobs, especially those that require confidence, problem solving, and persistence in the face of failure.

Researchers have also suggested that an optimistic approach to life and work leads individuals with high core self-evaluations to have higher expectancy motivation. Specifically, they are more likely to believe

their effort will lead to performance (expectancy) and that their performance will be rewarded (instrumentality), leading them to put more effort into their work. Both lab and field studies have documented links between core self-evaluations and self-reported motivation, as well as objectively assessed effort (time on task). Core self-evaluations may also influence job performance through coping. Under conditions of organizational change, both manager reports and independent reports of colleagues indicate that individuals with high core self-evaluations are better able to cope with change. Perhaps because they are happy on the job, motivated to work hard, and perform well, individuals with high core self-evaluations also tend to earn higher salaries and experience fewer career plateaus, less stress, and greater life satisfaction than do individuals with low core self-evaluations.

CORPORATE ETHICS

Corporate ethics can be defined in several ways: conceptually, operationally, officially, and actually. Conceptual arguments about the definition of organizational ethics focus on questions of stakeholder status and are defined by two theories, stakeholder theory and social contracts theory. Operational approaches to

increasing ethical behavior in organizations may be more or less proactive and are structured around organizational mission and legal compliance. Official ethical standards articulated by organizational leaders may include ethical codes, but they are arguably less important than actual ethical expectations, which are closely intertwined with organizational culture. Each of these approaches to understanding corporate ethics will be addressed in turn, followed by discussion of cultural differences in values that undergird ethical norms and codes of conduct. Social influences and organizational practices that may affect ethical behavior unintentionally or without reference to formal ethical controls will also be considered.

DISCIPLINARY APPROACHES AND DEFINITIONS

Scholarship in corporate ethics falls into two general disciplines: moral philosophy and social science. Moral philosophers approach corporate ethics by outlining ideals for how corporations and their managers should behave. Prescriptions for moral action and policy are the substance of this approach. That is, moral philosophers try to articulate the principles that organizations should adopt, regardless of the actual effectiveness of one or another approach. The social scientific approach, on the other hand, attempts to describe the social and psychological variables associated with moral action and, to a lesser extent, the effectiveness of ethical actions and policies. Synthesizing the larger, long-standing tensions between prescriptive and descriptive approaches, recent discussion among management scholars has attempted to combine these approaches.

Moral philosophy generally focuses on stakeholder theory, an outgrowth of classical social contracts theory. In its simplest form, social contracts theory argues that membership in work organizations involves tacit consent among parties to accomplish their purposes. Accompanying this basic consent among parties are obligations relating to attitudes and norms of conduct. That is, expectations about how people should approach tasks and how they should behave with one another are the substance of corporate ethics. Corporate ethics in this framework is defined in terms of people meeting obligations and maintaining expected conduct. Importantly, this philosophical definition does not rely on ethical expectations being openly stated or officially acknowledged.

In his critique of integrative social contracts theory, Robert Phillips argues that these unstated bases for social contracts do not adequately describe the content of social obligations. Following from recent political theory, stakeholder theory explores these issues further. First, the conditions that give parties a legitimate stake in organizational decisions—who has stakeholder status?—are a central concern in this theory. For example, do students have a legitimate stake in the decisions made by their professors about what they will teach? Should environmentalists be given a place in making a corporation's decisions about the resources the corporation uses? Second, an explicit norm of fairness is discussed in this theoretical application that answers the question, how are norms of conduct derived? Several approaches have been proposed. Stakeholder theory, therefore, is a derivative of social contracts theory, but it is concerned with these questions of stakeholder legitimacy and the derivation of norms through fair discourse. Using this framework, corporate ethics can be defined not only by obligations and conduct but also by the processes used for arriving at agreement about them.

Unlike moral philosophy, social scientific inquiry into the antecedents, nature, and consequences of ethical conduct in organizations has a short history. In social scientific inquiry, corporate ethics is defined in terms of the formal and informal expectations for organizational stakeholder conduct. The observation of actual corporate value structures and norms of conduct are central to this approach. These value structures are usually defined in terms of organizational culture and climate.

Initial studies describing the deliberate actions taken to effect ethical conduct in organizations uncovered the factors that lead organizations to control ethical behavior and the extent to which these ethical controls are embedded in actual organizational behavior. Beyond this, there is a large body of laboratory research in social psychology that has evaluated the social and individual predictors of factors such as helping behavior, obedience to authority, harassment, and prejudice. However, much less is known about the consequences of ethical controls in organizations, particularly with regard to their effect on organizational effectiveness and dysfunction in actual organizations. Paradoxically, this lack of evidence may result from the ethical difficulties associated with manipulation and control of antecedents of moral behavior in real-world settings.

EVIDENCE

Operationally, it is not clear whether social scientists and moral philosophers have taken different practical approaches to effecting ethical behavior despite their somewhat different conceptual approaches. Surveys show that more than 80% of U.S. corporations have formal ethical controls. These controls commonly include one or more of the following mechanisms: designation of ethics officers, formal codes of conduct, ethics committees and communication systems, training programs, and disciplinary processes. Descriptive research and research on the possible antecedents of ethical control systems strongly suggest that many controls result from compliance and conformity pressures rather than the organization's core values. That is, fears about lawsuits or bad publicity may be the motivating force behind ethical controls rather than attempts to infuse the organization with a broad commitment to ethical conduct. Top management's commitment to ethical controls, however, is predictive of the integration of formal ethical codes into organizational culture.

Still, treating ethics in a broad philosophical sense may have less influence on ethical behavior and outcomes than targeted approaches. In particular, evidence suggests that ethical codes of conduct by themselves have little effect on important outcomes, whereas targeted measures are likely to have some desired effects. Accountabilities in performance appraisals, guidelines for dealing with negotiations, regulations specific to particular types of unethical behaviors (e.g., harassment, discriminatory hiring), and similarly specific measures have been shown to relate to outcomes such as ethical breaches, ethical awareness, willingness to report violations, commitment to ethical conduct, advice seeking, and successful decision making and negotiating. Similarly, practices aimed at reducing particular types of unethical behaviors (e.g., discriminatory hiring, harassment, and stealing) have met with some success.

One way to distinguish among these organizational controls is to think of them in terms of whether they are aimed at *avoiding* ethical breaches through proactive mechanisms, such as awareness, commitment to ethical conduct, and establishing norms for advice seeking, or whether they seek to *manage responses* to breaches through reactive communication systems, reporting of violations to internal management, and so on. Organizations may benefit from

analysis of both proactive and reactive ethics policies and procedures.

In addition to these targeted approaches, the culture of the organization, its norms, and employee perceptions regarding fair treatment may support or hinder the effectiveness of formal codes of conduct. Although the evidence is scarce, it supports the notion that actual norms of conduct, organizational culture, perceptions of the fairness of organizational activities, and organizational climate all relate to the effectiveness of formal ethical codes. Not surprisingly, these actual aspects of corporate ethics have received more attention in the social scientific literature than in moral philosophical discussions.

It remains to be seen whether the differences in behavior associated with approaches to ethical conduct have any effect on organizations as a whole. The question here is whether “nice organizations finish last” or whether “virtue is its own reward.” This is a difficult question to answer given the conceptual and methodological challenges of studying ethics in organizations. Evidence about the fates of whistleblowers suggests that ethical breaches cost both the organizations that commit them and the people who report these breaches. This, in turn, suggests that managing to avoid ethical breaches may be more helpful than managing responses to them. Still, there is no direct evidence about the effects of ethical controls on the effectiveness of organizations, in terms not only of economic performance but also of the actual avoidance of dysfunction.

CULTURE AND ETHICAL CONDUCT

There is a growing awareness that corporate ethics is embedded within the broader cultural environment. It is important for decision makers to consider the reactions that are likely to arise from the blending of organizational codes and norms with the larger cultural environment, as broad cultural norms for what is and is not considered ethical conduct may not be the same as organizational norms and codes. For example, applying an existing corporate ethics code to a new international corporate office might prove problematic if the country hosting the new office has a very different basis for evaluating what is and is not ethical conduct.

SUMMARY

Whether organizations seek to define ethical conduct in a broad philosophical sense, describe current

ethical culture, effect change in specific ethical problems, or maintain an ethical culture and climate, it is sensible to consider all of these issues in both compliance and strategic discussions and practices. In particular, an awareness of actual ethical culture and climate is a useful starting place for enhancing organizational effectiveness.

CORPORATE SOCIAL RESPONSIBILITY

Questions about moral and political philosophy necessarily entail a consideration of political economy, which comprises two fundamental and overlapping concerns: the relationship between government and business and the relationship between business and society. It is the second relationship that has spawned the notion of *corporate social responsibility*—which comprises a firm's actions in that regard, or its

corporate social performance, and the corporate social orientation of its managers—as well as much scholarship concerned with social issues in management and business and society. With some oversimplification, they can all be distilled into the question, what are the societal responsibilities of businesses?

Although answers to this question tend to fall into one of two strongly contrasting models, Archie B. Carroll's taxonomy of the four domains of economic, legal, ethical, and discretionary or philanthropic responsibility provides a more nuanced approach. According to this approach, a firm's economic duty is to operate efficiently and profitably and to maximize shareholder value. It should do so while complying with the law and avoiding harmful civil litigation, as well as acting in accord with societal, business, and industry moral norms and expectations or formal codes of conduct. It should also act to promote the overall welfare of society and avoid doing harm. (Partly in response to theoretical criticisms, in recent writings, Carroll has eliminated discretionary philanthropy as a separate category and emphasized the overlapping nature of the three remaining domains. Philanthropy is included within both the ethical domain, as it is often ethically motivated, and the economic domain, because it is sometimes strategically motivated.) The two competing views of the proper relationship between business and society are the classical minimalist model of free enterprise capitalism and the revisionist free enterprise framework, in which corporate social responsibility plays a prominent role.

CLASSICAL FREE ENTERPRISE MODEL OF BUSINESS

The minimalist conceptualization of business responsibility originated in the economics of Adam Smith and the political philosophy of John Locke and, more contemporaneously, in the writings of the economist and social theorist Milton Friedman. The intellectual and moral justifications used in the model include *natural rights theory*, *social contract theory*, *utilitarianism*, and *enlightened ethical egoism*. The model views the maximization of shareholder value as the only legitimate responsibility of the corporation—reflecting the social contractual and property rights of shareholders to come together exclusively for that purpose, with as little intrusion as possible from government—as long as it abides by the law and the basic ethical

precept of not infringing on the rights of others. Because maximizing shareholder value is accomplished by efficiently and productively creating goods or services, society benefits overall. Using Carroll's taxonomy, a public corporation is conceptualized as having economic responsibilities but few legal and ethical responsibilities because it is absolutely required by law or custom to accomplish its economic aims. There are no legitimate discretionary or philanthropic responsibilities, an orientation characterized by Tom Donaldson as one of *ethical indifference*. (The owners of privately held companies are, however, free within this perspective to “foolishly” take on whatever social responsibilities they may choose.)

CRITIQUE OF THE CLASSICAL MODEL

Joel Lefkowitz summarized the four major scholarly criticisms of the minimalist model of business: (a) the tenuous justification for and moral deficiency of libertarian natural rights theory, which fails to acknowledge concepts that many believe are integral to the concept of morality—positive obligations and duties, beneficence, and justice; (b) the limited nature of property rights; (c) the unproven assumption that shareholders desire only short-term profit maximization; and (d) flaws in the application of utilitarianism (i.e., maximization of the overall net good for society) as a moral justification for free markets—for example, the absence of any perfect free markets and the restricted economic definition of what is “good.”

REVISIONIST FREE ENTERPRISE MODEL INCLUDING CORPORATE SOCIAL RESPONSIBILITY

According to Adolf A. Berle, Jr., and others, an upheaval took place during the second quarter of the 20th century, during which time corporations grew enormously, stock ownership became more widespread (hence diffuse), and shareholders became more separated from those who ran the firms. Management became more autonomous and powerful, with greater discretionary latitude. Opinion leaders such as U.S. Supreme Court Justice Louis Brandeis and social scientist Talcott Parsons advanced the notion that the occupation of the manager had become professionalized. One of the important distinctions between a profession and an occupation is that a profession has a putative concern for and sense of responsibility not

just to the paying customer or client but also to society at large. This enlightened concern for the well-being of society began to infuse conceptions of the role of manager and provided a basis for construing a sense of duty beyond that of profit maximization on behalf of shareholders—that is, corporate social responsibility.

The general rationale for corporate social responsibility is that, from a moral perspective, the modern corporation's power to do great good or great harm necessitates that it consider all of its direct and indirect effects on society. In addition, corporations are granted certain benefits by the state, such as limited liability for its owners and managers; indeed, as a legal entity, the corporation's very existence is created by the state. Corporations are also granted benefits by the communities in which they reside, such as clean air, police and fire protection, and transportation infrastructure. Therefore, they accrue reciprocal obligations to contribute to overall well-being. The classical business model applied social contract theory from political philosophy to the economic world of business to justify the voluntary association of shareholders to advance their profit motives. The revisionist model extends it further as the moral basis for the corporation's existence and the means of understanding its relationship to society. Two themes are apparent: As major institutions of society, organizations have a responsibility to (a) do good and contribute to the solutions of societal problems; and (b) take into account the interests of their many constituencies—those who are affected directly and indirectly by their actions—that is, their *stakeholders*. In other words, organizations are conceived as “citizens,” and good corporate citizenship may be displayed by implementing constructive corporate social performance and by engaging in proactive activities, such as enlisting in the United Nations Global Compact. The UN Global Compact is a voluntary enterprise that seeks to promote 10 principles of human rights, labor standards, environmental protection, and anticorruption initiatives for businesses (and other organizations) on a global scale.

Multiple Stakeholder Theory

Although it is marked by some definitional and theoretical difficulties, *stakeholder theory* is probably the most well-known version of the corporate social responsibility model. A stakeholder is generally

defined as any person, group, organization, or institution that can influence the focal organization or be affected by it, either directly or indirectly. Some constituencies are stakeholders by virtue of the organization's moral obligation to them, others because their strategic impact on the organization (and hence its other stakeholders) must be considered by the organization's decision makers. Each constituency—employees, customers, shareholders, the public, the media—may have a different stake in the organization, and the basic notion is that ethical and effective management of the organization entails recognizing and working with the legitimate, multiple, and often conflicting interests of different stakeholders. That approach is often referred to as a *strategic stakeholder approach to management*. The explicit concern for the interests and well-being of all stakeholders, including but not limited to the profit-maximizing objectives of shareholders, is what renders stakeholder theory moral in nature. As ethicist Wesley Cragg explained, corporations may be private entities, but they do have responsibilities to the public—they are accountable to multiple constituencies.

It has been observed, most notably by Donaldson and Preston, that there are three different kinds (or levels) of stakeholder theory that require different sorts of justifications. *Descriptive stakeholder theory* is the least controversial. Many, if not most, management scholars accept the empirical evidence supporting the conclusion that managers are sensitive to the interests of multiple constituencies and try to take them into account in decision making. *Strategic* or *instrumental stakeholder theory* concerns functional relationships regarding the consequences of behaving in that manner. It is eminently sensible to believe that managers would be wise to attend to all those who might affect the success of the firm. However, the evidence is insufficient and too equivocal to conclude that long-term organizational survival and effectiveness is significantly enhanced by explicit stakeholder management. *Normative stakeholder theory* holds that such an approach is a moral imperative—that organizations ought to be managed in that fashion. This is the level at which competing moral justifications for exclusive shareholder wealth maximization versus the multiple stakeholder model take place. The multiple stakeholder view is supported by the arguments summarized previously as well as by the meta-ethical principle of *universalism*, which holds that no one's (or no group's) interests take precedence over anyone

else's unless they are reasonably justified. Opponents hold that is precisely the point—that managers have a special fiduciary relationship to shareholders that gives the latter a superordinate moral status over other stakeholders.

CRITIQUES OF CORPORATE SOCIAL RESPONSIBILITY

There are several additional points of contention to consider:

- *Organizations cannot have moral responsibilities.* This view, articulated by business ethicist Manuel Velasquez, is not merely that organizations are not morally responsible or should not be held to have moral responsibilities but that they *cannot* be morally responsible because they lack the prerequisite attributes. Notwithstanding that the law, for some purposes, treats a corporation as an “artificial person” (e.g., it can sue and be sued), it is not a real individual entity with causal powers and intentionality. It is the presence of conscious, unified beliefs, motives, and intentions that permits an entity to be a moral agent. As Velasquez points out, the actions that we impute to a company are brought about by individuals, not by some metaphysical entity; when we attribute goals and intentions to a company, it is merely a metaphorical “as if” intentionality. From the perspective of corporate social responsibility and performance, even if this is true, it may be of no practical significance: Corporate social responsibility can simply be understood as pertaining specifically to the responsibilities and actions of organizational decision makers.

- *Vagueness and lack of clarity.* Both corporate social responsibility and stakeholder theory have been characterized as theoretically imprecise and operationally (i.e., pragmatically) indefinite. For example, there is some disagreement concerning the definition of who is a stakeholder, and distinctions have been made between primary and secondary stakeholders and moral versus derivative stakeholders. Most important for stakeholder theory, very little prescriptive advice or empirical evidence is available to guide the appropriate balance of multiple stakeholder interests. Are all stakeholders' interests to be considered equal? If not, what are the criteria for treating them equitably? What do we even mean by an *appropriate* balance? How should it actually work in practice? Similarly, what actions qualify as being socially

responsible? And how many of them are necessary to demonstrate adequate responsibility?

- *The relationship between corporate social performance and organizational effectiveness.* Because the outcome of the moral debate between the classic shareholder wealth maximization model and the revisionist corporate social responsibility model is largely indeterminate, attention has been paid at the instrumental level to whether the latter might actually contribute to the former (i.e., whether it pays, in terms of corporate financial performance, for an organization to behave in socially responsible ways). A great deal of empirical research has been conducted to address this issue. The good news is that reviews, including meta-analyses, of those studies support the view not only that there is a positive relationship between corporate social responsibility and financial performance but that it is a *causal* relationship from the former to the latter. But if one believes that the most important justification for the corporate social responsibility model is normative (i.e., moral) rather than strategic, then the bad news is that we are running the risk of reducing corporate social responsibility to merely another profit-maximizing strategy.

COUNTERPRODUCTIVE WORK BEHAVIORS

The term *counterproductive work behavior* (CWB) refers to a range of volitional acts at work that harm or intend to harm organizations and their stakeholders (clients, coworkers, customers, and supervisors). Such behaviors may be aimed at harming the organization (organizational deviance, or CWB-O), or they may be aimed at harming individual stakeholders inside or outside the organization (interpersonal deviance, or CWB-I). These behaviors range from relatively minor acts, such as purposefully doing work incorrectly or giving a coworker a dirty look, to severe acts, such as stealing expensive company property or physically assaulting a coworker. Other examples include threatening others, sabotaging equipment, committing physical assault, making offensive remarks, overreporting hours worked, isolating an individual so that he or she has difficulty working, stealing from the company, putting forth only minimal effort to avoid being fired, giving someone the “silent treatment,” failing to transmit information, and making obscene gestures.

Because of the importance of this topic to organizations and employees, researchers have devoted considerable attention to understanding the nature of CWB, its antecedents, and its consequences. Indeed, a variety of constructs that capture an array of counterproductive actions at work have been proposed. Here, the reader will be provided with an overview of CWB, including an understanding of the current debates that surround its definition, and a brief review of the antecedents and consequences associated with CWB.

DEFINITIONAL FEATURES AND CONTROVERSIES

There are two common ways in which the term *counterproductive work behaviors* is used: (a) as an umbrella term that summarizes a variety of related constructs and refers to a wide spectrum of negative acts at work; and (b) as a unique construct with definitional features that make it distinct from similar

constructs in the literature. Each of these perspectives will be reviewed in turn.

CWB as an Umbrella Term

Books and special issues of journals have used *counterproductive work behaviors* as an umbrella term to describe most negative actions that employees enact at work, which typically have negative consequences for their targets and for the organization. Other labels that describe the “dark side of the workplace” include workplace aggression, deviance, retaliatory behaviors, revenge, organizational misbehavior, violence, bullying, mobbing, harassment, emotional abuse, social undermining, incivility, abusive supervision, and petty tyranny.

Although there are distinctions among these terms that may warrant treating them as separate constructs, there is also a great deal of conceptual, empirical, and practical overlap. Measures of these constructs are often so highly overlapping that the items are nearly identical across scales. Moreover, a single negative act at work—for example, spreading a rumor about a coworker—may be labeled as an instance of CWB, aggression, deviance, revenge, bullying, incivility, and so forth. There are also cases in which constructs have distinct definitions, yet their measurement does not reflect all definitional characteristics (e.g., not measuring norm violations for deviance, not measuring intent for aggression). Thus, although these acts are conceptually distinct, the measurement of the constructs often makes them empirically identical. For these and other reasons, researchers argue that it is most parsimonious to use umbrella terms (such as CWB) to refer to this class of negative behaviors at work. However, this remains a controversial topic, and at least two other umbrella terms are used frequently in the organizational literature—*workplace aggression* and *workplace deviance*.

CWB as a Specific, Unique Construct

The term *counterproductive work behaviors* is also used to refer to a specific, unique construct that is distinct from similar constructs in the literature. Some scholars argue that CWB should *not* be used as an umbrella term that encompasses all negative acts at work because it does not encompass all of the dimensions on which negative acts at work may vary. These dimensions include the nature of the target

(i.e., individuals/organizations, organizational insiders/outside), the nature of the behavior (i.e., low severity/high severity/full range), the nature of the actor (i.e., organizational members/outside, supervisors/coworkers), the motive for the behavior (i.e., intent to harm/no intent/ambiguous intent, intent to restore justice), the violation of norms (i.e., required/not required, types of norms violated), the duration of the behavior (i.e., episodic/sustained over time), the outcomes of the behavior (i.e., negative outcomes/positive and negative outcomes), and the power differential between the actor and the target (i.e., required/not required, formal/informal bases of power).

As a specific, unique construct that is definitionally distinct from others, CWB refers to the full range (low severity to high severity) of negative actions enacted by organizational members, targeted toward organizational insiders or outsiders, that are either enacted with the intent to harm the target or intentional (nonaccidental). It is not necessary that any organizational or societal norms be violated, the acts need not be sustained across time, and there need not be any power differential between actors and targets. The term CWB implies negative consequences for individuals, the organization, or both, although this is a source of contention among scholars who argue that deviant acts, retaliation, or revenge may be productive and lead to positive outcomes. In summary, CWB may be used as an umbrella term that encompasses most negative acts performed by organizational members, yet it does not reflect all of the features of related constructs, and thus its usage as an overarching construct is still being debated.

ANTECEDENTS AND CONSEQUENCES OF COUNTERPRODUCTIVE WORK BEHAVIORS

Empirical research on CWB and related constructs (i.e., CWB as an umbrella term) has examined two distinct issues: (a) predictors of CWB and (b) outcomes of being the target of CWB-I. Regarding antecedents, CWB has been linked with several situational factors, including job-related stressors, organizational injustice, prior experiences of CWB, and group norms. Individual factors associated with enacting CWB include dispositional hostility, negative emotion, type A personality, impulsiveness, and substance or alcohol abuse. The second stream of research on the outcomes of experiencing CWB-I recognizes that CWBs are stressors for targets, and

stressors have psychological, health, and behavioral outcomes. Psychological outcomes include depression, anxiety, frustration, emotional exhaustion, poor psychological well-being, low life satisfaction, low job satisfaction, low organizational commitment, low job involvement, and perceptions of injustice. Health outcomes include somatic complaints and low health satisfaction. Finally, behavioral outcomes include enacting further CWBs, experiencing work–family conflict, and abusing alcohol or substances. In summary, this research demonstrates that both individual and situational predictors are important in the enactment of CWB and that experiencing CWB-I is associated with a range of negative psychological, health, and behavioral outcomes.

COUNTERPRODUCTIVE WORK BEHAVIORS, INTERPERSONAL DEVIANCE

Counterproductive work behavior (CWB) is any behavior that is intended to harm an organization or its members. Common types of CWB include theft, sabotage, aggression toward others, and spreading rumors. Behavior on the part of employees that is

intended to directly harm the organization, such as theft or sabotage, is commonly referred to as *organizational deviance* (CWB-O). On the other hand, behavior by employees that is intended to harm fellow employees, such as spreading rumors, harassment, violence, bullying, favoritism, gossip, blaming, and aggression, is referred to as *interpersonal deviance* (CWB-I). Researchers have used different terms to refer to such behaviors and to CWB in general, including abuse, aggression, bullying, deviance, retaliation, and revenge. On the surface, there are similarities between CWB-I and CWB-O, but empirical research has found that they are different.

WHY STUDY CWB-I

One important reason to study CWB-I is the negative effect it has on employees. The National Institute of Occupational Safety and Health found that approximately 20 employees are murdered and 18,000 are assaulted at work each week in the United States. Although most of these incidents are the result of robberies, some of them, particularly the nonfatal ones, are the result of aggression in the workplace. Incidents of aggression can cost employees money in medical bills and time lost from the job. Furthermore, even employees who are not the direct victims of such attacks may feel unsafe at work. This can have direct implications on job performance and absenteeism. Instances of CWB-I such as bullying, interpersonal violence, and harassment (including sexual harassment) cost organizations millions of dollars each year in lost work time, reduced job effectiveness, and lawsuits.

MEASURING CWB-I

A number of behavioral scales have been developed to measure the prevalence and seriousness of CWB. All are checklists that ask employees to indicate how often they have engaged in certain behaviors at work. One of the most popular scales is Sandra Robinson and Rebecca Bennett's Typology of Deviant Workplace Behavior. This scale divides CWB along two continuums, *organizational/personal* (CWB-O/CWB-I) and *minor/serious*. The organizational/personal continuum refers to the target of the behavior—the organization or other individuals working in the organization. The minor/serious continuum refers to how severe the consequences are. This scale allows us to

classify CWB within four quadrants: minor acts directed toward the organization, serious acts directed toward the organization, minor acts directed toward individuals, and serious acts directed toward individuals. Minor acts directed toward individuals might include showing favoritism, gossiping, blaming coworkers, and competing nonbeneficially. On the other hand, serious acts directed toward individuals might include verbal abuse, stealing from coworkers, and endangering coworkers. This scale and others similar to it allow us to investigate the antecedents of each type of CWB.

ANTECEDENTS OF CWB

Behavior is often considered a product of the person and the environment, and CWB-I is no exception: Employees commit CWB because of a complex web of personal and situational antecedents. Characteristics of the person, such as demographics and personality, and the work environment, such as the nature of work and relationships with others, combine to affect a person's behavior.

Environmental Antecedents of CWB-I

One important model, the *frustration aggression model* of CWB, is based on the classic frustration aggression theory. This model of CWB states that when employees experience frustrating events at work, they have an emotional response to the events. This emotional response often leads employees to behave in a way in which they can vent these emotions. This behavior may take the form of CWB. Thus, affective responses mediate the relationship between frustration and CWB. This model also hypothesizes that certain person characteristics, such as a sense of control, anxiety, and anger, affect this hypothesized relationship. Specifically, individuals who do not believe that they have a great amount of control over their environment and feel a sufficient amount of anger report higher levels of frustration and, in turn, often commit more acts of CWB. Additionally, an employee's perception of the likelihood of punishment is important. Employees who do not expect to be caught and punished are more likely to engage in CWB.

The *job stress model* of CWB builds on the frustration aggression model by focusing on different types of stressors rather than frustrating events. It

hypothesizes that stressful job conditions such as work constraints (things at work that interfere with completing job tasks, such as faulty equipment or insufficient training) or work overload (too much to do at work) lead to an emotional reaction, such as anger or anxiety. These reactions, in turn, lead to job strain, which includes both physiological reactions (e.g., increased blood pressure) and behavior intended to cope with the stressors. Sometimes, these behaviors are attempts to overcome the stressors in a productive way, such as by seeking help from a coworker or supervisor when there is insufficient time to complete a task. Other times, the response is a form of CWB, which may not solve the problem but may make the person feel better by venting his or her anger or other feelings.

Researchers have found support for the idea that negative emotions such as anger, guilt, nervousness, and fear do, in fact, mediate the relationship between stressors (job constraints and interpersonal conflict) and CWB-I. Therefore, individuals who perceive job constraints or have conflicts with others respond to these situations with negative emotions and, in turn, commit more acts of CWB-I. The job stress model also hypothesizes that a number of other variables influence the relationship between stressors and CWB. Specifically, researchers have found that the personality characteristics of trait anger (the tendency to respond to situations with anger) and trait anxiety (the tendency to respond to situations with anxiety) interact with job stressors to predict CWB-I. This means that employees who are high on trait anger and trait anxiety are more likely to respond to job stressors with CWB-I.

Although employees' stress levels and feelings of frustration play an important role in predicting whether they will commit acts of CWB, other researchers have focused on the role of justice. *Justice theories* of CWB state that employees who are not treated fairly are likely to engage in CWB. Researchers have identified two major types of justice, distributive and procedural. *Distributive justice* refers to employees' perceptions of whether rewards and punishments are distributed equitably within the organization. For example, do all individuals in the same position with the same length of tenure receive the same pay? *Procedural justice* refers to whether individual members of an organization view the policies and procedures by which rewards are allocated as fair. Although it seems intuitive that injustice would predict CWB-O—employees who feel they have been

treated unfairly would be likely to strike back at the organization—it has also been found to predict CWB-I. For example, the perceived level of procedural justice within an organization is related to the prevalence of CWB-I. Specifically, employees who perceive low levels of procedural justice within their organization tend to engage in more CWB against their fellow employees. An employee's emotions play a role in this relationship as well. Specifically, negative emotions mediate the relationship between procedural justice and CWB-I. Therefore, when employees perceive that procedures within their organizations are unfair, they tend to respond to this perceived unfairness with negative emotions, committing more acts of CWB-I.

Justice theories and stress or frustration theories are not mutually exclusive. Rather, empirical research has found that there are links between these theories and that both play important roles in predicting CWB-I within organizations.

Personal Antecedents of CWB-I

Researchers have found a number of personal antecedents of CWB in general and of CWB-I in particular. For example, employees who are high in trait anger and trait anxiety, hold strong attitudes toward revenge, are impulsive (have little self-control), and have been exposed to aggressive cultures are more likely to behave aggressively toward others in the workplace. Additionally, self-control moderates the relationship between anger and workplace aggression, such that individuals who experience greater amounts of anger and have less self-control are more likely to commit CWB-I.

Another line of research has examined the targets of CWB-I. One study found that employees who had a history of aggression and consumed alcoholic beverages were more likely to display aggression toward their coworkers. Additionally, the amount of alcohol an employee consumes interacts with his or her perceptions of procedural justice to predict aggression against a coworker or a subordinate. Specifically, employees who perceive low levels of procedural justice and consume alcohol are most likely to commit acts of aggression against their coworkers and subordinates.

WAYS TO REDUCE CWB-I AT WORK

Research has identified a number of antecedents of CWB, and it seems logical that paying careful attention

to these antecedents might reduce to the amount of CWB-I within organizations. One particularly important antecedent is procedural justice. Organizations should pay careful attention to the procedures they use to distribute rewards, such as pay increases, and ensure that policies affecting employees are seen as fair. This does not mean that every employee must receive the same salary or rewards but that, where there are differences, the reasons are based on a process that is considered fair. For example, pay based on sales commissions will typically result in pay differences, but employees often accept such systems as being fair. Maintaining procedural justice can help reduce the prevalence of CWB-I within an organization.

A second area of concern is workplace stressors, which can lead to CWB-I. For example, organizations should take steps to minimize organizational constraints by ensuring that employees have the materials and support they need to complete their jobs. This not only will result in better job performance (because constraints interfere with an employee's ability to do the job effectively) but also may reduce CWB-I. Furthermore, organizations should do what they can to minimize interpersonal conflict among employees. This can be accomplished by implementing policies and procedures concerning appropriate professional conduct at work and by training supervisors to handle and mediate conflicts between and with subordinates.

Although organizations should focus on preventing current employees from engaging in CWB-I, it is also important to consider CWB-I when hiring new employees, as some individuals are more likely to commit CWB-I than others. Specifically, individuals who have a record of poor or violent relationships with other employees and supervisors in the past and have poor self-control are more likely to commit acts of CWB-I. Additionally, empirical research suggests that certain types of screening tools, such as integrity tests, can be useful in predicting whether potential employees are likely to engage in CWB while on the job. Research has found such tests useful for predicting CWB overall, not just CWB-I.

SUMMARY

CWB-I is defined as behavior by an employee that is intended to harm his or her fellow employees. Examples of CWB-I include spreading rumors, harassment, violence, bullying, favoritism, gossip,

blaming, and aggression. It is important to study CWB-I because it negatively affects a large number of employees, as well as organizations, each year. The literature has identified a number of situational antecedents of CWB, including justice and job stressors. Additionally, a number of personal antecedents, such as self-control, trait anger, and trait anxiety, predict CWB-I.

COUNTERPRODUCTIVE WORK BEHAVIORS, ORGANIZATIONAL DEVIANCE

Counterproductive work behavior (CWB) refers to voluntary work behaviors that hurt or are intended to hurt the organization or its members. It includes acts

with potential harm, such as theft, physical aggression, and sloppy work. These behaviors are voluntary in the sense that they go beyond task performance, and their occurrence, form, and intensity is under the discretion of the individual. Some CWB is directed toward individuals in the organization (interpersonal deviance, or CWB-I); such behavior includes acts such as verbal assault, aggression, and spreading rumors. On the other hand, some CWB is directed toward the organization (organizational deviance, or CWB-O); such behavior includes acts such as theft, sabotage, work slowdowns, and withdrawal.

Like other types of harmful behaviors, CWB-O has drawn considerable attention among academicians and practitioners because it has many negative consequences for organizations and employees. Theft alone costs American organizations \$10 billion to \$200 billion annually. Additional losses are incurred from damage caused by sabotage and lower productivity (taking long breaks, wasting resources), which is difficult to quantify in dollar terms. Furthermore, CWB-O leads to an unsafe and insecure environment, which has adverse effects on the performance and well-being of the employees. Continuous occurrence of CWB-O may create a culture in which CWB-O can be more easily justified and committed more often by far more individuals.

MAIN CATEGORIES OF CWB

In terms of counterproductive work behavior, employees have a repertoire of acts to inflict harm. Although there are many ways to categorize CWB, the most popular taxonomy categorizes behaviors according to their target. Threats and abuse of others target people (e.g., coworkers), whereas work avoidance and sabotage target the organization. Overt acts such as theft may target both.

Sandra Robinson and Rebecca Bennett's Typology of Deviant Workplace Behavior classifies CWB, referred to as deviance, into two dimensions—interpersonal/organizational and minor/serious—producing four types of behaviors. Both interpersonal and organizational deviance may vary according to the severity of the acts. *Production deviance* concerns minor acts of violating organizational norms regarding the quantity and quality of work performed (e.g., being late or putting in little effort). *Property deviance* concerns serious acts of acquiring or damaging property belonging to one's employer (e.g., theft or

sabotage). Behaviors may include active or passive acts. Active behavior is immediately directed at a target (e.g., using a hammer to smash a piece of equipment). However, such overt harmful behaviors are visible and likely to be punished. Therefore, passive and indirect behavior (e.g., avoiding work) is more common.

ANTECEDENTS OF CWB

Like any human behavior, CWB is an outcome of the interaction between the environment and the characteristics of the individual. Both environmental and personal factors contribute to the occurrence and type of CWB. In most voluntary work behavior theories, an undesirable condition or event is present in the environment (e.g., injustice). People engage in cognitive appraisal and evaluate the situation. Then, they decide how to respond and may commit some type of CWB (e.g., theft or doing the work incorrectly). Personality plays a role in the way people perceive the environment and how they react. Therefore, the combination of certain environmental conditions and certain personality characteristics increases the likelihood of CWB.

Environmental Antecedents of CWB-O

The workplace environment consists of both the physical environment and the social or organizational context. In general, negative and stressful experiences, such as abusive supervision, problematic leadership, or incivility, lead to CWB-O.

One important antecedent of CWB-O is organizational constraints, or conditions that inhibit task performance (e.g., insufficient information or insufficient tools). When employees perceive constraints and cannot perform their jobs, they sometimes react by engaging in minor forms of CWB-O, sabotage, and withdrawal.

Negative situations may arise from the roles that employees play within the organization. *Role conflict* involves simultaneous demands that interfere with one another and make it difficult to carry out the job. *Role ambiguity* refers to the extent to which an individual is uncertain about what is expected from him or her. Both role stressors are related to tension and anxiety and increase the likelihood of CWB-O (e.g., sabotage and theft).

Justice, or the perceived fairness in the organization, is one of the most important antecedents of

CWB-O. Employees pay attention to how fairly rewards and punishments are distributed (distributive justice), how fair the policies and procedures are (procedural justice), and how well they are treated by their supervisors and management (interactional justice). When employees feel that they are being treated unfairly by the organization, they engage in more CWB-O. Moreover, the failure to explain a perceived injustice leads to an increase in theft and withdrawal.

Disagreements that employees have with other individuals in the organization are also associated with CWB-O. Employees may experience interpersonal conflict with their supervisors or with their coworkers. Although conflict seems to be interpersonal in nature, research has shown that conflict leads consistently to CWB against the organization.

Control is an important factor influencing CWB-O because it is related to one's ability to cope with threats and demands from the environment. When people perceive control over situations, they are less likely to engage in destructive acts and behave constructively. *Autonomy* refers to the control one has over decisions regarding work methods and scheduling. Employees who have more autonomy perceive more control and engage in fewer organizational forms of CWB.

When choosing their acts (e.g., CWB-O), employees also consider the psychological contract, which is the employee's belief that certain commitments and obligations exist between him or her and the employer. Such a contract concerns what is expected of the employee (e.g., attendance) and what the employee receives in return (e.g., salary). Any violation of the psychological contract by the organization is detrimental to the relationship between the employee and the organization and increases the likelihood of CWB-O.

Personal Antecedents of CWB-O

Individual characteristics affect the way employees behave in the workplace. In general, personal factors that increase or fail to diminish the effects of negative experiences may lead to CWB-O. The relevant personality characteristics are linked to experiencing emotions or to control of the environment or the self.

One important antecedent of CWB-O is trait anger, which refers to the dispositional tendency to perceive a wide range of situations as anger provoking. Employees who are high in trait anger react to undesirable situations more impulsively and with a greater

degree of anger. As a result, they are more likely to commit destructive acts and CWB-O.

Some individuals have a tendency to experience negative emotions across time and situations (negative affectivity). To the extent that employees perceive situations in the workplace in negative terms, they are more likely to engage in CWB-O. Additionally, individuals who are high in trait anxiety tend to perceive stressful situations as dangerous and threatening, so they have more frequent and intense negative emotional responses. Therefore, trait anxiety is associated with high levels of CWB-O.

Organization deviance may result from personality dispositions related to the lack or insufficiency of control. Self-control is the propensity to avoid acts whose long-term costs exceed momentary gains. People who have self-control are more successful in dealing with negative events in their environment. They can fine-tune their responses and avoid impulsive harmful behaviors. Therefore, the lack of self-control leads to CWB-O.

Another antecedent of CWB-O is locus of control, which refers to the tendency to attribute the causes of outcomes to either internal factors (the person) or external factors (the environment). People who believe that events happen because of factors that are outside their control are more likely to blame others (e.g., the organization) and commit CWB-O.

CWB MODELS AND THEORIES

In the CWB literature, there are different explanations and models explaining why people engage in CWB-O. At the core of most models, emotions and cognitions play important roles. In other words, the likelihood, the extent, and the form of CWB-O are influenced by how people feel and what people think. There are some overlaps between models, but each taps into different aspects of human nature and the environment.

According to the *emotion-centered stress model*, employees have to deal with many workplace stressors, which involve stressful events or situations (constraints on performance, role stressors, conflict, and injustice). When employees face stressors, they experience negative emotions (e.g., anxiety or hostility) and are more likely to engage in harmful behaviors, including CWB-O. The central role of emotions is to mediate the effects of environmental conditions on behavior. Job stressors (e.g., unfair treatment by the

organization) lead to negative emotions (e.g., anger), which then result in some type of CWB.

The *frustration-aggression model* holds that in the workplace, certain undesirable events (e.g., constraints) interfere with employees' goal attainment and therefore lead to frustration. When employees are frustrated, they try to overcome their negative feelings by committing some form of aggression, which may be directed toward people (CWB-I), inanimate objects, or the organization (CWB-O). When the frustration is caused by some organizational factor, people are likely to direct their CWB toward the organization. Moreover, frustration leads to more harmful behaviors when people believe punishment is unlikely.

Deviance in the organizational setting refers to violations of organizational norms, which exist for the well-being of the organization and are prescribed by formal and informal organizational policies and rules. According to Sandra Robinson and Rebecca Bennett's *deviant behavior model*, deviant employees either lack the motivation to conform to the expectations of the social context or become motivated to violate those expectations. Thus, CWB-O is considered a form of organizational deviance, which involves the violation of norms regarding the relationship between the employee and the organization. Production deviance involves the violation of corporate norms related to the creation of a product or provision of a service (e.g., putting in low effort), whereas property deviance violates norms related to maintaining and protecting property (e.g., sabotage or theft).

People perceive fairness when there is a balance between their contributions and the rewards they receive. According to Daniel Skarlicki and Robert Folger's *organizational justice theory*, people commit CWB to retaliate for an injustice by the organization. An employee who attributes responsibility for the injustice to the organization may engage in harmful behaviors to compensate for the wrongdoing and to "even the score." Although employees may retaliate when they perceive themselves as victims of unfair treatment by the organization, they also may react when they perceive others are being unfairly treated. In either case, the employee who sees injustice may experience anger and engage in CWB-O to retaliate against the organization.

PREVENTION AND CONTROL OF CWB-O

Our knowledge of the antecedents of CWB-O has led some researchers to develop practical solutions to

reduce it. Integrity tests, personnel screening, and preemployment testing can be used to identify applicants who are less prone to CWB, more conscientious, and self-controlled and therefore are less likely to engage in CWB. Organizations can avoid hiring applicants who have a history of aggression and show a personality pattern that is vulnerable to deviant behavior (high trait anger, negative affectivity, external locus of control, and lack of self-control).

Because injustice is one of the key antecedents of CWB-O, an organizational climate based on fair treatment is crucial. Employees should be treated with trust, respect, and dignity. In addition to providing adequate compensation, organizations should attempt to create and implement fair policies, rules, and procedures. Support for employees, employee assistance programs, and training in conflict management skills are also helpful. Furthermore, the organization should take steps to reduce job stress. Conditions and events (e.g., organizational change or salary cuts) that lead to negative cognitive and emotional responses should be taken into account in managerial actions. Moreover, such actions should be communicated to employees properly so that they understand the rationale and reasons for them. Other ways of reducing CWB-O include setting an example for employees, presenting role models, communicating a policy concerning counterproductive behavior, and consistently and fairly punishing unacceptable behavior (e.g., theft).

SUMMARY

Counterproductive work behaviors against the organization are voluntary acts that hurt the organization, such as theft, sabotage, or doing a job incorrectly. The presence of CWB-O has negative consequences for organizations (e.g., financial loss from theft) and for employees (e.g., poor well-being). Most research has focused on determining who is likely to engage in CWB and under which conditions. Such behavior is believed to result from a combination of personality factors (e.g., trait anger, trait anxiety, and low self-control) and environmental factors (e.g., constraints, injustice, and conflict).

CREATIVITY AT WORK

Current definitions of creativity focus on the outcome, that is, an idea or product that is original as well as useful. However, early work in the area of creativity focused on the creative individual and creativity in the domains of art and science. Research during this early period was directed primarily at understanding major breakthroughs and paradigm shifts (also known as *big C creativity*). Current conceptualizations include minor creative acts involving incremental change and adaptation (known as *little c creativity*), suggesting that creativity can occur in almost any job. Models of creativity in organizations focus on individual antecedents of creativity, organizational or contextual

factors that hinder or facilitate individual creativity, and the interaction within and between the two.

INDIVIDUAL CREATIVITY

Early models of creativity focused on individual characteristics that facilitate creativity. Though different models may emphasize one element or set of elements, most agree on the key components that facilitate individual creativity: (a) cognitive processes, (b) domain-relevant knowledge and skills, (c) personality variables, and (d) motivational variables.

Cognitive Processes

Michael Mumford and his colleagues have identified several core cognitive processes that contribute to creative problem solving. *Problem construction*, or problem identification, is the first step in the creative problem-solving effort. Because problems that allow for creative solutions are ill defined, the problem-construction step is particularly important. Ill-defined problems, which are common in organizational settings, are those in which multiple goals and means of solving the problem are possible and multiple solutions exist that are possible and acceptable. This ambiguity facilitates creativity but also necessitates problem construction. The problem solver must first identify the important goals and information required to solve the problem, as well as any restrictions on the solution. Research on problem construction suggests that it is an effortful and time-consuming process and that engaging more actively in the problem-construction process results in more creative solutions.

After the problem has been defined, the problem solver must search for the *information* needed to solve the problem. This information may already be available to the problem solver, or it may need to be obtained from external sources. Once obtained, the problem solver must combine this information in new ways before a creative solution results. Research findings again indicate that the cognitive processes required for this step necessitate a large commitment of time and effort. In addition, the quantity and diversity of information available to the problem solver from this step may facilitate creativity, up to a point. Too much information, especially irrelevant information, will hinder creative performance.

A third core process that is necessary for creativity—and one of the most-researched cognitive

processes—is *idea generation*, which is typically measured using divergent-thinking tests. In organizations, idea generation is often called *brainstorming*. Much of the empirical work on divergent thinking and brainstorming has focused on fluency, or the number of ideas, as the main way to evaluate idea generation. However, it is clear that just having a large quantity of ideas is not necessarily related to having good or creative ideas. Research has shown that providing instructions on the goals of the idea generation focuses the attention of the problem solver on that goal, resulting in different outcomes based on the instructions. Instructions to be creative, flexible, or original increase the creativity, flexibility, and originality of the ideas generated, respectively. Instructions to focus on one goal at a time lead to more solutions but ones that only solve for that goal, whereas instructions to solve for two conflicting goals result in fewer solutions but more complex ones that attempt to solve both issues presented. Instructions seem to provide a way to evaluate ideas and therefore determine whether the ideas generated match what is needed. However, very little research has explored the idea-evaluation process specifically.

Finally, later phases of creative problem solving necessitate cognitive processes that facilitate *implementation planning* and *monitoring*. This includes the generation of contingency plans for the implementation of the idea and the monitoring of the actual implementation to make changes as necessary. Although both implementation planning and monitoring are cognitive in nature, the actual implementation and carrying out the changes needed because of monitoring involves more social processes, and therefore they are typically viewed as innovation (the implementation of a creative idea).

Domain-Relevant Skills and Knowledge

Creativity cannot occur in a vacuum. Studies have shown that domain-relevant knowledge is required for the generation of novel and useful ideas. An individual must have a foundation on which to develop a creative idea. However, it has been suggested that a high degree of expertise may lead to habitual performance, thereby hindering creativity. In addition, diverse information may be beneficial for creativity because it helps to break the rigidity of thinking that can result from too much knowledge in any given area.

Therefore, the ideal level of knowledge required for creativity is believed to fall somewhere between the novice and expert levels.

Personality

Research in this area has investigated the relationship between personality variables and creative performance. Openness to experience, a component of the five-factor model, has been most consistently linked to creative performance across domains. Creative individuals are often described as independent, persistent, introverted, curious, self-confident, driven, impulsive, and tolerant of ambiguity. In addition, several personality variables have been linked to creative performance in one domain but not another. For example, a meta-analysis reviewing studies on personality and creativity revealed that creative scientists tend to be more conscientious and closed-minded relative to noncreative scientists and creative artists, whereas creative artists tend to be more emotionally unstable and reject groups norms relative to both creative and noncreative scientists.

Attitudinal variables have received limited attention in creativity research; however, research that does exist suggests that they are important. Studies have shown that individuals who have a preference for ideation, value new ideas, and delay premature closure are able to generate more creative ideas. Attitudes toward creativity may provide the motivational force to apply the cognitive processes needed for creative performance.

Motivation

Theresa Amabile's seminal work on the effect of motivation on creativity suggests that intrinsic motivation is critical for creative performance. Providing rewards may hinder creativity by creating an extrinsic as opposed to an intrinsic motivation. However, current research suggests that not all external rewards have a negative impact. External rewards may provide informational or controlling cues. Informational cues let the individual know what is important and improve performance, and therefore they increase intrinsic motivation. Controlling cues focus the attention of the individual on the external reward and evaluation, thereby contributing to extrinsic motivation.

ORGANIZATIONAL CREATIVITY

Job and Team Characteristics

An important factor that distinguishes the study of creativity at work from other forms of creativity is the focus on context. Studies focusing on organizational factors suggest that complex jobs characterized by high levels of autonomy allow for more creativity. In addition, organizational creativity has more social and financial constraints than other environments in which creativity is studied. Because of the social and collaborative nature of creativity in organizations, group and leader effects have been the focus of research on creativity in this area.

Most teams in organizations comprise members with different expertise (i.e., cross-functional teams), which can both facilitate and hinder creativity. Research has suggested that teams that have a diversity of knowledge and skills but still share common goals are more creative. In addition, because information must be shared and the problem facing the team is ill defined (that is, there is no right or wrong solution), open communication that allows for disagreement and collaboration among group members is important. These factors point to the importance of team climate in facilitating creative performance. Teams and organizational climates that facilitate trust, open communication, risk taking, and support for creativity have been found to facilitate creative performance.

Leadership

Organizational leaders play an important role in creating the climate of the work group and the organization. Numerous studies have found that leaders who are supportive, provide informational (nonjudgmental) feedback, and involve employees tend to facilitate creativity. Transformational leaders have been found to facilitate creativity more than transactional leaders. In addition, leaders, as boundary spanners and gatekeepers, provide resources and remove obstacles. Leaders may facilitate creativity by providing team members with the time and financial resources necessary for creative performance. Leaders may also facilitate smooth information exchange with other organizational units. Another important role provided by leaders (although not exclusively) is that of role modeling. Research suggests that observing a creative role model may allow an observer to learn creativity-relevant skills and strategies and model how they

should be implemented. Finally, leaders may serve in the role of champion, supporting the efforts of both team members and other members of the organization.

OUTCOMES

Only limited empirical work has been conducted on the outcomes of creativity. Creativity and innovation typically serve as criteria of interest, not as predictors. Creativity has been linked to the implementation of innovative ideas and patents, to increased organizational flexibility and adaptability, and to organizational growth and increased profit. However, models of organizational creativity stress that much of the impact of creativity may not be realized in the short term and may actually hurt short-term performance. Specifically, factors that contribute to creativity may hurt day-to-day productivity. Not only do employees need to invest time and resources in the creative process, taking away from time and resources invested in current operations, but also the same factors that facilitate performance in routine tasks, such as structure, attention to detail, and conformity, can hinder creative performance.

FOSTERING CREATIVITY

Understanding what contributes to creativity allows us to determine what organizational policies and practices to enact to foster it. Much of the empirical work on enhancing and fostering creativity has focused on training. How training is structured and what content is taught is based, in part, on the framework used to understand creativity. Creativity training that focuses on cognitive processes—most notably, divergent thinking and brainstorming—has been found to be successful. In addition, creativity training directed at the attitudinal and motivational aspects that contribute to creative performance or the social interaction patterns that facilitate creativity has shown promising results. A meta-analysis of more than 70 studies of creativity training found that creativity training as a whole is effective, and training focusing on cognitive processes produces the best and most consistent results.

Surveys of organizational practices indicate that companies are using selection systems to identify creative talent prior to hiring; however, research on the efficacy of such practices is lagging. Other recommendations include redesigning organizations and

jobs to create more complex jobs in which employees have more autonomy and opportunity to show creative performance. Again, very little research has been conducted in this area. The use of rewards, either monetary or through performance appraisal, has also been suggested as a way to enhance creative performance. Rewards must be perceived as informational and not controlling in order to have the desired effect; however, the factors that contribute to the perception of rewards or performance appraisals as informational are not well delineated.

Organizational interventions designed to enhance creativity include improving the organizational culture and climate. Specifically, creating an environment that supports creativity by allowing for risk taking and openness and providing the resources necessary will foster creativity. Other organizational interventions include creating diverse, cross-functional teams and facilitating knowledge and information sharing through technologies such as knowledge management software. Virtual teams have been suggested as one way to facilitate creative performance because they may allow for greater diversity and acceptance of individuals from different backgrounds. Finally, leaders are viewed as an important facilitator of creativity at work. Finding or training an individual who can lead creative employees successfully will facilitate the creative performance of individuals and teams.

CREDENTIALING

Credentialing is a process for granting a designation, such as a certificate or license, by measuring an individual's competence in a specific knowledge, skill, or performance area. The purpose of credentialing is to assure the public that an individual meets the minimum requirements within an area of competence, typically an occupation or profession. There are three principal types of credentialing. *Licensure*, the most restrictive type, refers to the mandatory government requirement needed to practice an occupation or profession. The second type, *certification*, is a voluntary process that is traditionally established by nongovernmental agencies. The final type of credentialing, *registration*, is the least restrictive and typically requires individuals to apply for a credential through a governmental or private agency.

Although registration credentials are usually a mandatory process, individuals are not required to demonstrate a level of achievement beyond the application for a title. Licensure and certification, on the other hand, require an individual to successfully complete an educational program or demonstrate relevant job experience, as well as complete a test or assessment. Despite the distinctions between licensure and certification, the development process for these two types of credentials is similar.

IDENTIFYING CREDENTIALING EXAM CONTENT

The first step in developing a credentialing exam involves gathering information to demonstrate that the exam content is directly linked to the occupation of

interest. This is known as *content validity*. The most common approach for content validating a credentialing test is using an occupational analysis (also known as a practice analysis). An occupational analysis differs from a job analysis in that it focuses on an entire profession rather than a specific job. One of the most critical decisions during the occupational analysis for a credentialing exam is defining the targeted level of expertise to be tested. If the examination is designed to credential practitioners who possess the minimum level of required competence in an occupation, the analysis should focus only on entry-level requirements. However, if the examination targets intermediate or expert practitioners, particular attention should be given to identifying the level of competence to be targeted by the examination. Although a variety of techniques exist for gathering occupational analysis information, all occupational analyses should rely on input from individuals who are deeply knowledgeable about the profession.

Regardless of the occupational analysis technique employed, the results should be used to develop the credentialing exam's content outline (also known as a test blueprint). The content outline is used to convey the organization of the exam by describing the content domains covered on the exam, as well as the amount of emphasis given to each content domain. Most credentialing exams contain many content domains, which are traditionally organized by similar tasks, knowledge areas, or skills. The amount of emphasis given to each content domain should reflect the findings of the occupational analysis—that is, the domains identified as most important in the occupational analysis should receive the most emphasis on the exam, whereas domains of lesser importance should receive a smaller amount of weight. A well-developed content outline should not only guide the development of the test questions but also facilitate candidates' preparation for an exam.

DEVELOPING THE CREDENTIALING EXAM

Many different question formats can be used on credentialing exams. Test developers traditionally use the results of the occupational analysis to identify the most appropriate format(s) for an exam. Multiple-choice questions are the most commonly used format for credentialing exams, particularly for exams that focus on measuring knowledge domains. An extensive amount of research supports the

effectiveness of this type of question for credentialing exams.

However, for many credentialing programs, the multiple-choice format may not be the most effective way to gauge an examinee's proficiency. Other viable formats include performance-based assessments and simulations. Performance-based assessments are intended to elicit responses with more than one correct answer and with multiple dimensions. For example, a physician's credentialing exam might include questions that require an examinee to identify multiple ways to diagnose and treat an illness. Because of the open-ended nature of these questions, the grading is often done by subject-matter experts (SMEs). Simulations present an occupational-related scenario that is measured under standard conditions. For example, a flight simulation might offer an effective test format for some content areas on a pilot certification exam. Simulations are often scored using a standardized checklist or rating process to ensure that all raters are properly calibrated.

Regardless of the format, the process for developing a credentialing exam remains the same. The first step is to assemble SMEs to write test questions or to inform the structure of a performance assessment or simulation. The SMEs should represent the specialty areas within the occupation and have expertise in the content domains measured on the exam. The SMEs should then be provided with training on how to write test questions. The training should review the relevant components of the exam specifications, acceptable question formats, and techniques for developing effective questions. Because effective question writing is an iterative process, each question typically goes through an extensive review by the SMEs. Once the questions have been reviewed, a different group of SMEs content-validates the questions. This process involves reviewing each question to ensure the accuracy, importance, and suitability of the content in relation to the target areas on the exam outline. Questions that are deemed acceptable are pilot tested to obtain preliminary data, and questions with acceptable pilot test data are then used to construct an exam that conforms to the test specifications. Each of these steps depends heavily on the involvement of SMEs to ensure accurate representation of the content areas in the exam, as well as an industrial psychologist, psychometrician, or similarly trained measurement professional to oversee the process and conduct many of the more technical tasks.

SETTING PERFORMANCE STANDARDS

Once an exam is developed, defining the passing point on the exam becomes of primary importance. There are two broad categories of standard-setting techniques. The first category involves the use of *normative standards*. With this technique, pass/fail decisions are made by comparing a candidate's performance to the performance of other candidates. This technique is common in many personnel selection situations, in which the goal is to select the best from many candidates who may be qualified; however, it is rarely used for credentialing because it guarantees that some examinees will fail regardless of whether candidates demonstrate an acceptable level of competence. Because of this issue, nearly all credentialing programs rely on the second category of techniques that use absolute standards.

In their simplest form, *absolute standards* offer a policy statement about what constitutes acceptable performance on an exam (e.g., all candidates with a score above 70% will pass). However, this technique fails to account for the actual level of performance required for competent practice, the difficulty of the exam, or the characteristics of the candidate population (e.g., it is possible that all candidates sitting for an exam are competent). Typically, a more appropriate method for setting an absolute performance standard is to include a strategy for linking decisions about examination performance to criteria for acceptable practice of the profession. This involves the use of a criterion-referenced approach, which sets performance standards by evaluating the test content and making judgments about the expected or observed candidate performance. The most commonly used method for accomplishing this is the Angoff method, although several variants and alternative methods exist. These methods ensure that candidate test performance is directly linked to a minimum performance standard of the profession.

TRENDS IN CREDENTIALING

Cultural pressures are placing greater demands on individuals and organizations to be accountable for their competence, performance, and results. These pressures have prompted an increase in the use of testing and assessment to gauge educational outcomes and have now extended into the realm of occupational certification. There are signs that the certification of

competence is of increasing importance in business organizations. Software developers have long been able to take credentialing exams to demonstrate competence in specific computer languages. Hiring organizations may then factor these measures into their selection requirements. Some companies even use a form of credentialing in their career management systems—for example, by requiring a passing score on a competence assessment before applying for promotion. By using properly constructed examination processes to establish competence, organizations are better able to make fair and accurate workplace decisions about individuals.

CRITERION THEORY

A core interest of personnel psychology is whether some intervention in selection, training, or motivation relates to some criterion. A *criterion* is an evaluative standard that is used as a yardstick for measuring employees' success or failure on the job. In many instances, the criterion of interest will be job

performance, but a criterion could also be a particular attitude, ability, or motivation that reflects an operational statement of goals or desired outcomes of the organization. Implicit in this definition is that the criterion is a social construct defined by organization leaders who are responsible for formulating and translating valued organizational outcomes.

THE ULTIMATE CRITERION

Eventually, we are interested in predicting the *ultimate criterion*, that is, the full domain of employees' performance, including everything that ultimately defines success on the job. Given the totality of this definition, the ultimate criterion remains a strictly conceptual construct that cannot be measured or observed. To approach it, however, and to describe the connection between the outcomes valued by the organization and the employee behaviors that lead to these outcomes, J. F. Binning and G. V. Barrett introduced the concept of *behavior–outcome links*. In practice, these links should be based on a thorough job analysis, in the form of either a job description that analyzes the actual job demands or a job specification that reveals the constructs required for good performance.

THE OPERATIONAL CRITERION

The conceptual nature of the ultimate criterion requires practitioners to deduct and develop the criterion measure or *operational criterion*, an empirical measure that reflects the conceptual criterion as well as possible. Using this operational criterion as a proxy for the conceptual criterion of interest, the usual approach in personnel psychology is to establish a link between performance on a predictor and performance on the operational criterion as an indication of the predictor's criterion-related validity. Operational criteria might include the following:

- Objective output measures (e.g., number of items sold)
 - Quality measures (e.g., number of complaints, number of errors)
 - Employees' lost time (e.g., occasions absent or late)
 - Trainability and promotability (e.g., time to reach a performance standard or promotion)
 - Subjective ratings of performance (e.g., ratings of knowledge, skills, abilities, personal traits or characteristics, performance in work samples, or behavioral expectations)
- Indications of counterproductive behaviors (e.g., disciplinary transgressions, personal aggression, substance abuse, or voluntary property damage)
- In practice, operational criteria should satisfy at least three independent requirements.
1. Operational criteria must be relevant to the organization's prime objectives. Although this may sound obvious in theory, in practice, criterion choices are often based on convenience (e.g., using data from performance records that are "lying around anyway"), habit, or copying what others have used. Though recorded output data such as sales volume might be easily accessible, they may represent a more suitable criterion measure for some organizations (e.g., car dealers striving for high momentary sales figures) than for others (e.g., car dealers living on good word-of-mouth propaganda resulting from superior customer service).
 2. Operational criteria must be sensitive in discriminating between effective and ineffective employees. This requires (a) a linkage between performance on the operational criterion and the employee's actual performance on the job (i.e., the link between the operational and the conceptual criterion) and (b) variance among employees. Speed of production, for example, may be an unsuitable criterion in cases in which speed is restrained by the tempo of an assembly line; likewise, the number of radioactive accidents is likely to be low across all nuclear power plant engineers, making this theoretically relevant criterion practically useless.
 3. Operational criteria need to be practicable, as the best-designed evaluation system will fail if management is confronted with extensive data recording and reporting without seeing an evenly large return for their extra efforts.

THE CRITERION PROBLEM

The *criterion problem* describes the difficulties involved in conceptualizing and measuring how the conceptual criterion of interest, a construct that is multidimensional and dynamic, can best be captured by an operational criterion. This problem, according to Binning and Barrett, is even bigger if the job analysis on which the criterion is based is of poor quality and if the link between the operational and the conceptual criteria has been weakly rationalized.

CRITERION DEFICIENCY AND CONTAMINATION

Any operational criterion will suffer from at least one of two difficulties: First, criterion deficiency is a formidable and pervasive problem because operational criterion measures usually fail to assess all of the truly relevant aspects of employees' success or failure on the job. Second, operational criteria may be contaminated because many of the measures are additionally influenced by other external factors beyond the individual's control. One of the most persistent reasons a measured criterion is deficient is the multidimensionality of the ultimate criterion, which combines static, dynamic, and individual dimensionality. Two other reasons for both contamination and deficiency are the unreliability of performance and performance observation. Finally, reasons associated primarily with criterion contamination are stable biases influencing criterion evaluations.

Static dimensionality implies that the same individual may be high on one facet of performance but simultaneously low on another. Thus, although an employee may do terrific work in terms of classical task performance (i.e., activities that transform raw materials into the goods and services produced by the organization or that help with this process), the same employee may show relatively poor contextual or organizational citizenship behaviors (i.e., behaviors that contribute to the organization's effectiveness by providing a good environment in which task performance can occur, such as volunteering, helping, cooperating with others, or endorsing and defending the organization to outsiders). Even more, the same individual might engage in counterproductive behaviors or workplace deviance (i.e., voluntary behaviors that violate organizational norms and threaten the well-being of the organization and its members, such as stealing, avoiding work, or spreading rumors about the organization).

Another aspect of static dimensionality addresses whether performance is observed under typical performance conditions (i.e., day-in, day-out, when employees are not aware of any unusual performance evaluation and when they are not encouraged to perform their very best) or under maximum performance conditions (i.e., short-term evaluative situations during which the instruction to maximize efforts is plainly obvious, such as work samples). The distinction is

important because performance on the exact same task can differ dramatically between situations, not only in absolute terms but also in terms of employee ranking of performance. A likely reason is that typical versus maximum performance situations influence the relative impact of motivation and ability on performance.

Temporal or dynamic dimensionality implies that criteria change over time. This change may take any of three forms. First, the average of the criterion may change because performers, as a group, may grow better or worse with time on the job. Second, the rank order of scores on the criterion may change as some performers remain relatively stable in their performance while others highly increase or decrease their performance over time. Third, the validity of any predictor of performance may change over time because of changing tasks or changing subjects. The changing task model assumes that because of technological developments, the different criteria for effective performance may change in importance while individuals' relative abilities remain stable (e.g., a pub starts accepting a new billing method and expects employees to know how to handle it). Alternatively, the changing subjects model assumes that it is not the requirements of the task but each individual's level of ability that change over time (e.g., because of increased experience and job knowledge or decreasing physical fitness).

Individual dimensionality implies that individuals performing the same job may be considered equally good, but the nature of their contributions to the organization may be quite different. For example, two very different individuals working in the same bar may end up with the same overall performance evaluation if, for example, one of them does a great job making customers feel at home while the other one does a better job at keeping the books in order and the bills paid.

Criterion reliability, the consistency or stability with which the criterion can be measured over time, is a fundamental consideration in human resource interventions. However, such reliability is not always given. More precisely, there are two major sources of unreliability. Intrinsic unreliability results from personal inconsistency in performance, whereas extrinsic unreliability results from variability that is external to job demands or the individual, such as machine downtimes, the weather (e.g., in construction work), or delays in supplies, assemblies, or information (in the case of interdependent work) that may contaminate

ratings at some times but not necessarily at others. Practically, there is little remedy for criterion unreliability except to search for its causes and sample and aggregate multiple observations over the time and over the domain to which one wants to generalize.

Besides lack of reliability in the criterion itself, *lack of reliability in the observation* is another cause of discrepancy between the conceptual and the operationalized criterion—that is, the criterion measurement may result in very different results depending on how it is rated and by whom. Thus, objective data and ratings by supervisors, peers, direct reports, customers, or the employee may greatly diverge in their evaluations of an employee's performance for diverse reasons. Although an employee's direct supervisor may seem to be the best person available to judge performance against the organization's goals, he or she may actually observe the employee only rarely and thus lack the basis to make accurate judgments. Such direct observation is more frequent among peers, yet relationships (e.g., friendships, coalitions, in-groups versus out-groups) among peers are likely to contaminate ratings. Direct reports, in contrast, primarily observe the evaluated individual in a hierarchical situation that may not be representative of the evaluated individual's overall working situation, and, if they fear for their anonymity, they, too, may present biased ratings. For jobs with a high amount of client interaction, clients may have a sufficiently large observational basis for evaluations, yet they may lack the insight into the organization's goals needed to evaluate the degree to which employees meet these goals.

Operational criteria can be contaminated because of diverse errors and *biases*. Error, or random variation in the measurement, lowers the criterion reliability and is best addressed through repeated collection of criterion data. Biases, however, represent a systematic deviation of an observed criterion score from the same individual's true score. Because they are likely to persist across measures, biases may even increase statistical indications of the operational criterion's reliability. If the same biases are equally related to the measure used to predict the criterion (e.g., performance in a specific personnel selection procedure), they may also increase the predictor's statistical criterion-related validity, even though this validity is not based on the actual criterion of interest but on the bias persisting across measurements.

Among the diverse possible biases, biases resulting from knowledge of predictor information or group membership and biases in ratings are particularly prominent. If, for example, a supervisor has been involved in the selection of a candidate, his or her impression during the selection process is likely to influence the evaluation of this candidate's later fit or performance on the job. Group membership may incur bias if the organization provides support to some groups but not others (e.g., management training for women only) or if different standards are established for different groups (e.g., quota promotions). Finally, biases in criterion ratings may result from personal biases or prejudices on the part of the rater, from rating tendencies (leniency, central tendency, or severity), or from the rater's inability to distinguish among different dimensions of the criterion (halo). These effects will become more severe as employees' opportunities to demonstrate their proficiency become more unequal and as the rater's observation becomes more inaccurate.

CRITICAL INCIDENT TECHNIQUE

The critical incident technique is a research process that invites respondents to identify events (incidents) they deem significant (critical) for a particular purpose, typically associated with job performance within an occupation. Researchers use data from participants' accounts to form categories of behaviors that contribute to the success or failure of a given purpose.

HISTORY OF THE METHOD

John C. Flanagan is credited with developing the critical incident technique, originally in connection with studies of World War II aviators (part of the Aviation Psychology Program, out of which emerged the American Institute for Research). Flanagan and his colleagues were interested in why pilots in training fail their programs, how pilots respond when they become disoriented, and what leads to failed bombing missions. His research technique permitted him to efficiently gather multiple instances of the behaviors in question and analyze those incidents for patterns. The research technique has since been applied to a wide variety of occupations, activities, and perspectives.

CRITICAL INCIDENT TECHNIQUE FIVE-STAGE PROCESS

Most researchers using the critical incident technique employ some version of the five stages of the process that Flanagan articulated. In brief, the researcher (a) establishes the general aims of a particular activity; (b) specifies the precise conditions to be observed (or recalled); (c) collects data in the form of interviews or questionnaires that elicit relevant incidents; (d) analyzes the data; and (e) interprets and reports the findings.

An example may help to clarify the stages of the critical incident technique: Suppose that an executive in charge of a chain of movie theaters is interested in the best way to train managers. A common problem that such businesses face arises when unruly crowds of younger patrons create disruptions as they reach a critical mass. To better understand how managers might address this, a researcher asks theater managers to recount incidents in which they were effective or ineffective in minimizing such disruptions.

Stage 1: Establish Aims

In the first stage, the researcher defines the aims of the activity. This step lays the groundwork for determining what constitutes a critical incident. In general, an incident consists of an account, either from the direct experience or the observations of the participant, that relates closely to the aim of the activity.

Although a theater manager may have many aims (e.g., drawing in more young adolescents, efficiently moving crowds between showings, increasing concession sales, training employees), the aim in question focuses directly on one particular challenge: preventing or stopping young people from disrupting the theater experience of other patrons. The behavior that is critical in succeeding in this aim is not the same behavior that is critical for enticing more young adolescents to patronize a given theater. Flanagan indicated that it is often helpful at this stage to involve experts in defining the aim, particularly for activities that do not involve supervisors or when stakeholders define the aim differently.

Stage 2: Specify Plans and Conditions

The second stage in the process involves clearly specifying the conditions that address the general aim and the plans for collecting incidents. The researcher defines the situation to be observed, who is being observed, and who will make the observation. In our example, the young patrons are in the theater as opposed to waiting in line to purchase tickets; the theater has a mixed audience, not one composed exclusively of young adolescents; the behavior of one group of patrons is potentially disruptive to another; and the manager is the one who takes action. These conditions allow judgments to be made about the relevance of the behavior described.

In addition to the conditions, the researcher must determine who is best qualified to provide incidents. Generally, this requires familiarity with the conditions and behaviors. For the sample study, theater managers are uniquely qualified because they make choices about their behaviors in the context described. However, potential observers might also include patrons or other employees.

Stage 3: Collecting Critical Incidents

Next, the researcher must collect critical incidents. Many researchers prefer to gather oral accounts through the critical incident interview, but written accounts may also be collected. A sample protocol might include the following questions: "Think of a time when one of your theaters had an audience with a concentration of young adolescents whose behavior

threatened or disrupted the viewing enjoyment of other patrons. Could you please describe the situation? What did you do (or what did you observe a manager do) to minimize the disruptions? Why was this particularly effective (or ineffective)?” The researcher continues this line of questioning, probing the interviewee for specific details. One interview may elicit numerous incidents because a manager may have encountered this particular situation often.

A key consideration in this technique is the number of incidents that must be collected. Generally, more complex activities require a greater number of incidents. The range of incidents in published studies is quite large (from fewer than 20 to more than 4,000). Flanagan indicated that one should continue collecting incidents until new incidents provide few or no additional critical behaviors.

Stage 4: Analyzing the Data

Data analysis occurs in conjunction with collecting incidents (because the final count of incidents is affected by the emerging analysis). Researchers create categories of behavior that are relevant to the purpose of the study or the way the data will be used. In the sample study, the researcher would develop categories of behavior that assist or impede the management of the problem in the theater situation. The analysis is intended to help design training programs for managers (or possibly selection criteria). A different aim would require a different frame of reference for the analysis. Given this general frame of reference, analysis then moves to the formation of categories and subcategories of similar behaviors, a step that Flanagan acknowledged as subjective. Coding (categorizing) of data is an inductive process of comparing statements and grouping by patterns.

Stage 5: Interpreting and Reporting Findings

In the final stage, the researcher interprets and reports findings. Again, much of this report depends on the targeted use of the study. The report should clearly indicate the aim that has been studied, particularly if competing aims are present. Reports commonly include both the weight of the categories (i.e., percentage of comments) and the language used by respondents.

APPLICATIONS

The critical incident technique has been usefully employed to analyze behaviors, techniques, traits and characteristics, interactions, and even thought processes in a tremendous variety of occupations. The technique can form the basis for selection criteria, evaluation tools, and professional development, either as the foundation of training programs or as the actual mechanism for training if employees participate in the creation and analysis of critical incidents.

CROSS-CULTURAL RESEARCH METHODS AND THEORY

Research in industrial and organizational (I/O) psychology is increasingly being conducted across cultural boundaries to test the generalizability of Western findings and to train managers to be more effective in multicultural contexts. Although cross-cultural research involves many of the same methods that are used in typical I/O research, many unique issues arise in the cross-cultural research process—from the level of theory to the sampling of people, constructs, and

methods to the analysis and interpretation of data—each of which will be discussed here.

DEVELOPING CROSS-CULTURAL RESEARCH QUESTIONS: LEVELS OF ANALYSIS

Cross-cultural research is inherently multileveled, and the first step in any cross-cultural research project is to decide on the level of analysis that is inherent in the research question. By way of illustration, Figure 1 shows the levels of analysis that might be involved in studies of societal culture. Societal culture reflects variation across societies in values, norms, beliefs, and assumptions, among other elements (see Table 1 for descriptions of how societal cultures vary). Linkages A and B in Figure 1 represent *single-level* models, which examine the macro antecedents and consequences of national culture. Linkages C through E represent *cross-level direct effect* models, which examine the direct effect of societal culture on organizations and individuals. Linkages

F through I represent *cross-level moderator effect* models, which examine how societal culture moderates relationships at the organizational and individual levels. Later, we will give illustrations of cross-cultural research questions that span these multiple levels of analysis. (Note: The dashed arrows in the figure are not discussed for reasons of space.)

Macro Antecedents and Consequences of Societal Culture

Linkages A and B represent research on the antecedents and consequences of societal culture at the macro level. Cross-cultural psychologists have long argued that societal cultures develop through adaptations to the ecological, historical, and sociopolitical context. Accordingly, one might examine how factors such as temperature, natural resources, population density, economic structure, or a history of conflict between nations affect societal values, norms, or beliefs. Research may also focus on culture’s

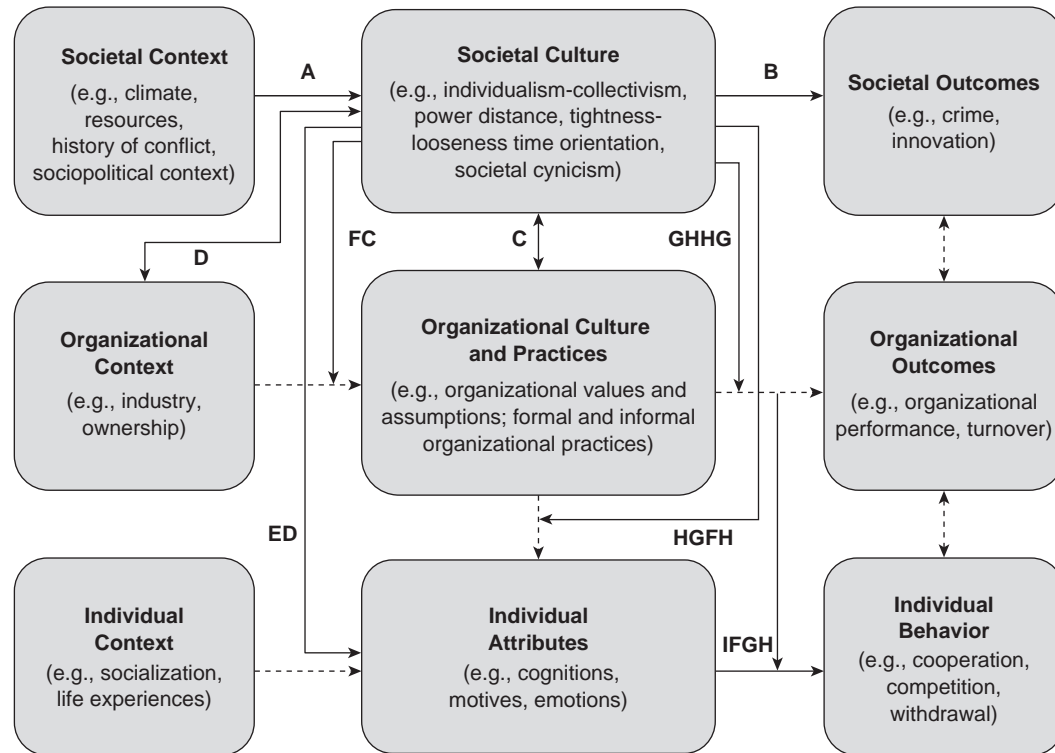

Figure 1 Levels of Analysis in Cross-Cultural Research

<i>Societal Dimension</i>	<i>Authors</i>	<i>Description</i>
Beliefs/assumptions	Bond, Leung, et al. (2005)	Societal cynicism: General mistrust of social systems and other people Dynamic externality: Proaction in the face of external constraints
Values	Hofstede (1980)	Individualism: Degree to which people in societies maintain loose ties and look after themselves rather than exist within strong, cohesive in-groups Power distance: Degree to which people in societies expect and accept an unequal distribution of power Uncertainty avoidance: Degree to which people in societies feel threatened by uncertain and ambiguous events Masculinity/femininity: Degree to which gender roles are distinct and emphasize material success over quality of life
	Schwartz (1994)	Conservation versus autonomy: Emphasis of group embeddedness over autonomy Autonomy can be further subdivided into intellectual autonomy (pursuit of intellectual freedom) versus affective autonomy (pursuit of positive emotional experiences) Hierarchy versus egalitarianism: Mechanisms for coordination, either through hierarchical social roles that ensure responsible behavior or through voluntary, commitment-based moral obligations Mastery versus harmony: Striving toward mastery and control over the social and physical world versus acceptance and subjugation to preserve the social order
	Kluckhohn and Strodtbeck (1961)	Human nature: Are people evil, good, or mixed? Man–nature relationship: Should people subordinate, harmonize, or dominate nature? Time: Are people past, present, or future oriented? Activity: What is the best mode of activity—being, becoming, or doing? Social relations: What is the best form of social organization—hierarchical, collateral, or individual?
	Ingelhart (1997)	Traditional versus secular-rational orientations toward authority Survival versus self-expression values
	Chinese Culture Connection (1987)	Confucian work dynamism: Discipline, thrift, and persistent work (also referred to as long-term versus short-term orientation)

Table 1 (Continued)

<i>Societal Dimension</i>	<i>Authors</i>	<i>Description</i>
	Smith, Dugan, and Trompenaars (1996)	Particularistic relations based on ascribed status versus universalistic relations based on achievement Loyal involvement (toward family) versus utilitarian involvement (individual responsibility)
Norms	Pelto (1968), Berry (1967), Triandis (1989), Gelfand, Nishii, and Raver (in press)	Tightness/looseness: Degree to which norms are clearly defined and reliably imposed
Language/communication	Hall (1959, 1976)	High- versus low-context communication: Degree to which the meaning of communications is direct and explicit (e.g., contained in the message) versus indirect and implicit (e.g., read through the context, such as through silence, body posture, and facial expressions) Proxemics (communication of space) and paralinguistic communication (eye behavior, gestures) Polychronic versus monochronic use of time in communication (processing multiple tasks or few tasks simultaneously)

consequences at the societal level, for example, examining how societal values, norms, or beliefs affect societal crime rates, conformity, or innovation.

Cross-Level Direct Effects of Societal Culture

Research questions may be concerned with the cross-level direct effects of societal culture on organizations and individuals. Scholars in I/O psychology recognize that organizations are open systems that reflect and adapt to the larger societal context. This is reflected in Linkage C, or cross-level research that examines the influence of societal culture on organizational culture. Other research at this level of analysis might examine how societal culture affects the human resource practices—such as selection and job analysis techniques, performance appraisal methods, and training methods—that are implemented in organizations. Research might also examine the indirect effect of societal culture on organizational outcomes as mediated by cross-cultural differences in organizational culture and practices. Finally, Linkage D in

Figure 1 represents research that examines how societal culture directly affects the institutional context of organizations. For example, research might examine whether the prevalence of certain industries or ownership structures (e.g., private versus public) varies across societies.

Although Linkages C and D represent societal cross-level effects on organizations, Linkage E represents research that examines how societal culture affects individual-level phenomena, such as cognitions, motives, or emotions. Research in I/O psychology, for example, has examined how societal culture affects employees' achievement motivation, self-efficacy, job attitudes, and perceptions of effective leadership. Alternatively, one might be interested in the indirect effect of societal culture on individual behavior as mediated by individual perceptions, motives, or emotions. For example, research might examine whether there are cross-cultural differences in cooperative behavior in negotiations, teams, or organizations (e.g., organizational citizenship behaviors) as mediated by cross-cultural differences in individuals' perceptions, attitudes, or motives.

Cross-Level Moderator Effects of Societal Culture

Cross-cultural research questions focus on how societal culture moderates relationships at lower levels of analysis. Linkage F represents cross-level research that examines how societal culture interacts with features of the organizational context (e.g., industry, technology) to predict organizational culture and practices. For example, one might be interested in whether organizational cultures are more similar across societies within some industries (e.g., manufacturing) as compared with others (e.g., services). Linkage G illustrates that the relationship between organizational culture and practices and organizational outcomes can be moderated by societal culture. Research might examine whether the success of implementing different practices (e.g., innovation versus quality control) varies across societies. Alternatively, research might address whether diversity in organizations is beneficial for organizational performance and how this relationship varies across societies.

Figure 1 illustrates the moderating effect of societal culture on relationships at lower levels. For example, Linkage H represents research on the way societal culture moderates the impact of organizational practices on individual cognitions, motives, or emotions. Research might address, for example, whether giving voice (an organizational justice practice) has similar effects on satisfaction in different societal cultures or whether working in teams similarly affects motivation across cultures. Finally, Linkage I illustrates that societal culture moderates the relationship between psychological states and behavior. For example, research might examine whether societal culture moderates the strength of attitudes as a predictor of behavior or whether needs (e.g., the need for closure) differentially affect behavior across cultures.

Figure 1 illustrates the complexity of levels of analysis in cross-cultural research. Accordingly, before conducting cross-cultural research, it is important to specify the level at which the theory is operating and implement a design and analysis strategy that matches the level of theory. Figure 1 need not represent all possible multilevel linkages that pertain to societal culture. For example, research might focus on how societal culture affects variance at multiple levels of analysis rather than just mean differences. Figure 1 also does not include indigenous research questions,

which are interested in examining emic (culture-specific) phenomena that may not be applicable beyond a certain cultural context.

Sampling Participants

After deciding on a research question and determining the appropriate level of theory, the next step is to determine which cultures, organizations, or individuals to include in the research. As in unicultural research, these decisions should ideally be guided by theory. For example, if the researcher is testing a theory that relates one or more dimensions of culture to organizational phenomena, cultures should be sampled so that there is wide variation along those dimensions. Quantitative and qualitative data sets on cross-cultural differences abound and can be consulted when making sampling decisions. Conducting cross-cultural organizational research is further complicated by the need to consider the similarity of organizations and individuals within organizations across cultures. If a sample contains individuals from industry A in one culture but individuals from industry B in a second culture, culture is confounded with industry, thus creating an alternative explanation for observed cultural differences. Matching industry, as well as individual characteristics such as job level or other demographics, across cultures can reduce alternative explanations for observed cross-cultural variation.

Assessing the Constructs of Interest

After deciding on a sampling strategy, researchers need to consider how they will assess the constructs of interest. Typically, researchers rely on what J. W. Berry calls *imposed etic constructs*, or constructs that are developed in one culture and simply applied to another culture. Ideally, researchers should consider whether there is *construct contamination* and *construct deficiency* to avoid comparing apples to oranges in cross-cultural studies. Consider a construct that is developed in culture A and then applied to culture B. It is possible that the construct will be contaminated with aspects of culture A that are not meaningful in culture B. To assess the possibility of construct contamination, researchers might use factor analytic techniques to determine whether the factor structures are invariant across cultures. Even if the construct is not contaminated, however, it may possess construct deficiency in culture B if there are culture-specific (emic)

aspects of culture B that are not encompassed by the etic construct. Pilot studies and feedback from local collaborators are critical to identifying missing elements of constructs. An alternative approach is to develop an emic instrument without regard to other cultures and then compare results using the local instrument with results using instruments developed elsewhere.

Sampling Methods

A wide range of methods are available for cross-cultural research, and each has particular advantages and disadvantages.

- Laboratory experiments provide a controlled research environment and facilitate tests of causal assumptions. Laboratory research is also beneficial because it enables the researcher to assess implicit attitudes in addition to explicit self-reported attitudes. Yet it is critical to ensure that laboratory tasks and procedures are equally understood and motivating to individuals across different cultures. Extensive pilot testing, coupled with detailed feedback from local collaborators, can help to ensure that the laboratory situation is equivalent across cultures.
- Questionnaires may be less intrusive than laboratory experiments, and they provide the ability to collect data on a wide range of questions at any one time. Cross-cultural challenges to surveys abound, however, including potential differences in motivation, understanding of instructions, validity, reliability, and response sets. Pilot testing, discussions with local collaborators, and statistical controls are critical to ensuring equivalence.
- Interviews and focus groups enable researchers to gain depth in a research question and afford more of an understanding of emic perspectives that are especially useful in the early stages of cross-cultural research. Difficulties may arise, however, in standardizing interviews across cultures, and there may be differential reactions to the interviewer across cultures (e.g., women interviewing men may be viewed as inappropriate in some cultures) that can threaten the validity of the results. Interviewers should possess characteristics similar to those of the participants, and cross-validating interview findings with additional methods is critical for gaining confidence about the results.
- Cultural documents such as newspapers, proverbs, or speeches provide useful and unobtrusive cross-cultural data that can be content analyzed. Researchers should involve local collaborators to

identify documents that are most relevant to the research question, to ensure the comparability of documents across cultures, and to develop detailed coding schemes that are reliable and valid across cultures.

- Observations of behavior can provide an unobtrusive method for collecting cross-cultural data. Researchers, however, should confer with local collaborators to ensure that the observed situation has equivalent meaning across cultures. Furthermore, as with cultural documents, detailed coding schemes and hypothesis-blind coders are necessary to produce reliable data.
- Large archival databases provide another unobtrusive source of cross-cultural data. Examples include ethnographies, which provide in-depth information about a given culture, and cross-cultural databases on ecological, sociological, economic, or political variables. Preexisting databases, however, may only be available for a limited number of countries or variables. Furthermore, at times, the researcher may not be sure of the extent to which the data set is characterized by errors or biases, making the use of multiple sources critical to establishing validity.

In sum, many methods for cross-cultural research exist, and all have distinct advantages and disadvantages. Moreover, each method varies in terms of how appropriate or ethical it is in a particular cultural context, how much depth it affords, and ultimately, its validity and reliability across cultures. In light of these complexities, feedback from local collaborators, as well as the triangulating across multiple methods, is critical in cross-cultural research.

Translations

The most commonly employed cross-cultural research methodologies often require translating materials into other languages. Translation, however, may result in variations in meaning across cultures. The translation-backtranslation technique is often used in cross-cultural research to examine problems with translations. In this method, an individual translates materials from the original language to a second language. A second individual then retranslates the material back into the original language, and the two versions are compared to reveal any meaning that was lost in translation. Although frequently used, the translation-backtranslation methodology may result in awkward translations. Another option is to use the “decentering”

approach. In decentering, changes are made simultaneously to the original and the translated version to improve the quality of the materials in both languages.

Assessing Rival Hypotheses

When conducting research across cultures, extraneous variables that may influence the results should be measured and controlled. R. S. Malpass referred to these variables as *rival hypotheses* and noted that they are often unaccounted for in cross-cultural research. For example, asking people about their own opinions may be more commonplace in some societies than others, or people may be differentially motivated to please experimenters across societies. Cultural differences in perceptions of the method, task, or instructions can also affect results. In his studies of Kpelle farmers in Liberia, Joseph Glick showed that participants were able to sort objects in the “Western intelligent” way (i.e., by taxonomic category) compared to the “superficial” way (i.e., by color), but only when they were told to sort the objects in the “stupid” way! Pilot tests and discussion with local collaborators are critical to identifying which rival hypotheses need to be measured or controlled.

Analyses and Interpretations

Unique issues arise in the analysis and interpretation phases of cross-cultural research. Fons Van de Vijver and Kwok Leung addressed such issues by establishing equivalence and dealing with response sets. Cultural response sets, or systematic tendencies in the use of response scales, can pose a rival hypothesis for substantive results. In some societies, individuals may avoid the extremes of the scales, whereas in others, individuals may be more likely to show agreement. Additionally, people in different societies may be thinking of different reference groups when answering questions. Van de Vijver and Leung, as well as Kaiping Peng and colleagues, discuss a number of techniques to deal with such issues, including the use of different response formats, standardization techniques, or structural equation modeling to correct for response biases. Finally, when testing hypotheses, it is critical to align the level of theory with the level of data analysis and to avoid making ecological fallacies, wherein a phenomenon at a higher level of analysis is attributed to a lower level.

SUMMARY

Cross-cultural research adds a number of complexities to the research process that require additional informed judgment calls at all research stages. Although the task appears formidable, using multiple methods, extensive piloting, and feedback from collaborators can greatly increase confidence in the findings.

CUSTOMER SATISFACTION WITH SERVICES

This entry provides an overview of some of the key scholarly developments in the area of customer satisfaction with services over the last 25 years. The service sector now dominates employment and gross domestic product figures for the United States and, more broadly, the economically developed world. However, this overview applies beyond the service sector, as some have argued that all firms are service businesses because manufactured goods are typically augmented by related services. Furthermore, increasing numbers of high-profile manufacturers, such as General Electric and ABB, aspire to increase their percentage of revenues from services.

SERVICES AS AN AREA OF STUDY: A MULTIDISCIPLINARY EVOLUTION

Contemporary academic interest in services—conceptualizing services and related theory building, as well as how to measure customer satisfaction with services—blossomed during the late 1970s (as opposed to much earlier definitions and commentary on service in organizational sociology and economics). The emergent interest focused on how goods differed from services and grew out of a multidisciplinary perspective comprising marketing, organizational behavior, industrial and organizational psychology, and operations management. This multidisciplinary approach underscores how all functions in an organization must work together to satisfy a customer.

The three disciplines contributed to a specification of how the prototypical “pure” service (such as education in the classroom) differs from the prototypical “pure” good (such as a television set) in both production, consumption, and consumer evaluation processes. Compared with goods, services are typically described as possessing relative intangibility, heterogeneity, perishability, inseparability of production and

consumption, and customer participation in coproducing the services consumed. Each discipline has addressed how the nature of services should influence both theory and practice in their field.

Marketing

The academic field of marketing not only helped to pioneer the specification of how services differ from goods; it also drove the assessment of service quality and customer satisfaction from a technical approach to what has been labeled a user-based approach. The technical approach bases quality assessment on conformance to objective and readily measured standards set for the attributes of the output, and thus it is best suited to measuring the quality of mass-produced standardized goods.

The user-based approach assumes that quality is more subjective and therefore more appropriately measured from the perspective of the user or customer. This better fits the intangible, experiential nature of many services. Specifically, goods and services vary in their search, experience, and credence qualities. Prototypical services possess few easily observed search qualities (e.g., color and hardness) but instead are characterized more by experience qualities (e.g., taste) and difficult-to-evaluate credence qualities (e.g., characteristics that customers may need to accept on faith, such as the adequacy of a will). In turn, experience-based intangibility provides limited objective reference points for assessing the value of services, makes it difficult to quantitatively measure output and service quality, and makes it difficult to set specific, clear goals for employees.

The earliest model—and arguably the most visible measure of quality from the user’s perspective—SERVQUAL, was developed by three pioneering services marketing researchers, A. Parasuraman, Valarie Zeithaml, and Leonard Berry. This model and survey of service quality assesses five dimensions—reliability, empathy, assurance, responsiveness, and tangibles—using a gap model that measures both expectations of how the service should occur and perceptions of what actually happened. These same five dimensions have not always emerged in studies done by other researchers; indeed, the original authors themselves stated that SERVQUAL and its factors may not be unconditionally applicable for all types of service situations.

Service Quality, Customer Satisfaction, and Customer Loyalty

The marketing literature conceptualizes service quality and customer satisfaction as different but interrelated constructs. The consensus is that service quality is a judgment about a service's overall excellence (more descriptively and factually assessed), whereas satisfaction is a summary assessment of how the service emotionally affected the customer (more evaluative). There has been debate about the causality between the two; the consensus view is that service quality is an antecedent of satisfaction.

Measurement issues have blurred the distinction between the two constructs because SERVQUAL uses the unmet expectations gap model that originated in the customer satisfaction literature. There is also debate about which expectations standard is most appropriate; the predictive standard of "most likely to happen" tends to be used for satisfaction, and the excellence standard tends to be used for service quality. Finally, the measurement issues associated with difference scores (e.g., poor reliability, weak discriminant validity, and restricted variance) are relevant to measures of both constructs because both use the gap model.

Customer satisfaction with services appears to have only weak to modest relationships with other business outcomes of interest, such as customer retention and profitability. It appears, for example, that satisfied customers may defect anyway. This has led researchers—and practitioners in particular—to focus on the conceptualization and measurement of customer loyalty as the construct that relates most strongly to profitability. However, the strength of the relationship between loyalty and profits has also been questioned. Finally, for a brief period, service researchers attempted to specify more emotional and needs-based assessments of service using the construct of customer delight, which was of keen interest to practitioners for a while, as well as customer outrage. Overall, more research on the relationship among dependent variables in services is needed.

Organizational Behavior and Industrial/Organizational Psychology

A principal contribution to the area of services and customer satisfaction is the construct *climate for service*, which evolved from Benjamin Schneider's study

of the organizational climate in banks some 30 years ago. Climate for service is the shared perception of policies, practices, procedures, and the behaviors that get rewarded, supported, and expected with regard to customer service and customer service quality. Service climate represents the degree to which the internal functioning of an organization is experienced as one that is focused on service quality.

The climate for service "shows" to both service employees and customers, given the commonplace physical and psychological closeness between the two. Early research on this phenomenon found strong, significant relationships between employee experiences of service climate and customer perceptions of service quality. This was a departure from previous management thought and practice, which had divorced internal climate from customer experiences. In contrast, these results demonstrated that customer perceptions could be another criterion for validating employee perceptions of the workplace. One example of an application of this is the use of customer data (e.g., customer perceptions of service quality or customer satisfaction) to determine which human resource management practices (e.g., training, hiring, or compensation), as evaluated by employees, correlate most strongly with customer outcomes or dimensions of the climate for service (as perceived by customers). These findings were advanced further by the development of the *service profit chain* by researchers at the Harvard Business School. This work documented the relationships between employee satisfaction with internal service and those employees' productivity in creating service value for customers, customer satisfaction and loyalty, and firm profitability and growth.

This work on shared employee and customer climate-based perceptions has continued in a program of research termed *linkage research*, which has benefited from ongoing contributions from Schneider and his colleagues and others. A common focus in linkage research is the boundary conditions that moderate the strength of relationships between employee and customer outcomes (i.e., determining when linkages between employee and customer outcomes are strongest). For example, the frequency of contact between employees and customers and the length of employee or customer tenure with the organization are variables that might be positively associated with strong employee–customer linkages.

Linkage researchers have also had to resolve methodological and data analytical issues. Because

the unit of analysis is typically an organizational subunit rather than the individual, it is necessary to appropriately match employees and customers by unit and then apply the appropriate aggregation statistics (see Schneider and White, 2004, for a review of alternatives).

Finally, there is the issue of causality between employee and customer outcomes. Early conceptualizations tended to assume that causality flows from the employee to the customer—that is, employee attitudes are formed in the workplace in response to the perceived climate for service and spill over to customers. However, it also seems possible that customer attitudes could shape employee attitudes. For example, a popular adage holds that it is more enjoyable to serve a satisfied customer than a dissatisfied customer. The causality question has received little attention, though one study that specifically tested for this using a cross-lagged panel analysis found support for a reciprocal relationship between employee climate perceptions and customer perceptions of service quality.

Operations Management

Operations management, in theory and in practice, contends with how organizations make choices in the apparent trade-off between marketing effectiveness (meeting customer demands in ways that meet customer expectations of responsiveness and empathy and also influence customer perceptions of service quality and customer satisfaction) and operations efficiency (meeting demand in a cost-effective way that provides customers with the prices they expect and the margins the firm needs).

Ironically, it is customer contact with the service operation—customer presence in the service facility and customer participation in coproducing the services they receive—that is a principal source of tension surrounding these choices. Customer contact enhances the firm's ability to leverage marketing opportunities, but on the other hand, customer contact can also introduce input uncertainty and variance into the operations of the core technology.

This trade-off can be resolved in a win-win manner (marketing effectiveness *and* operational efficiency) if customer participation can be managed in a way that customers perform their coproduction roles as expected. This challenge can be met if service firms enhance the same individual-level variables in coproducing customers that influence the

performance of employees: role clarity, motivation, and ability. In other words, coproducing customers must understand what tasks they are expected to perform in service production and be willing and able to do so. Finally, it also appears that when customers perform their roles well, their overall satisfaction level is higher.

LOOKING AHEAD

Many advances have been made in the area of service in the last 25 years, but today, the scholars who led those advances are calling for a new paradigm to guide future theory building and research. Much of the work to date has been stimulated by a specification of the unique characteristics of service and their implications for theory and practice, and it has relied on certain models and methods such as the gap model of service quality and linkage research. One concern is that the alleged differences between goods and services seem overstated, and consequently, the associated implications overdrawn or tired.

This new services paradigm remains unstated or at least unsettled. The possibilities are most visible in the marketing discipline, in which recent research has argued that it is time for the discipline to embrace a service-dominant foundation. In the fields of organizational behavior and industrial and organizational psychology, there seems to be less visible and focused effort to set a new paradigm for services and customer satisfaction, and thus there are ample opportunities for researchers in this area to join and direct future services research.

CYBERLOAFING AT WORK

The term *cyberloafing* refers to employees' use of Internet and e-mail services provided by their employer for nonwork purposes during working hours. In other words, it is a high-tech method for employees to shirk their job duties while appearing to be working. Cyberloafing may include e-mailing jokes to friends, online shopping or game playing, downloading music, instant messaging, posting to newsgroups, or surfing non-work-related Internet sites. These behaviors, also called *cyberslacking* or *cyberslouching*, are even encouraged by some Web sites (e.g., www.ishouldbe-working.com). Cyberloafing is an important issue facing organizations as more employers are providing employees with Internet and e-mail access at work.

PREVALENCE OF CYBERLOAFING

One third of the time that individuals spend on the Internet takes place at work, and over half of that time is not work related. A survey by Vault.com indicated that almost 88% of employees surf non-work-related Web sites during working hours, and 66% surf between 10 minutes and one hour. Likewise, 82% of employees send non-work-related e-mails during work hours and nearly 87% receive them. The most commonly accessed Web sites at work involve game playing, investment or stock trading, shopping, adult activities, sports, job hunting, and gambling.

PROBLEMS ASSOCIATED WITH CYBERLOAFING

Although the Internet and e-mail have changed the way organizations do business by offering rapid communication and enhanced information access

and distribution, cyberloafing can create problems for companies. Employees can flood computing resources with their personal use, leading to clogged bandwidth and degraded system performance. Furthermore, cyberloafing reduces productivity, creates security issues, and increases the risk of computer viruses. It also exposes companies to legal liability in the form of harassment (e.g., employees e-mailing sexist or racist jokes to coworkers), copyright infringement (e.g., employees using clip art found on the Internet without permission), defamation (e.g., disgruntled workers posting rumors about a manager in a chat room), and negligent hiring (e.g., an employee cyberstalking a customer).

REASONS FOR CYBERLOAFING

Few research studies have explored reasons why employees cyberloaf, but in general, they indicate that it is a response to mistreatment in the workplace. For example, a study by Vivien Lim, Thompson Teo, and Geok Leng Loo found that Singaporean employees agreed that cyberloafing is justified when they put in extra effort to attain the information or resources they need to perform their jobs, work overtime without compensation, are asked to do excessive amounts of work, or are exposed to conflicting demands. Likewise, a study by Lim using the same Singaporean employees discovered they were more likely to cyberloaf when they perceived unfair treatment by their employer (e.g., unfair work outcomes, policies, or interpersonal interactions).

More recently, Christine Henle and Anita Blanchard demonstrated that employees engage in cyberloafing more often when they perceive their jobs as stressful. Thus, cyberloafing helps employees cope with stressors in the workplace. Importantly, employees are less likely to use cyberloafing as a way of coping with stress when they perceive organizational sanctions against it (e.g., discipline). Unfortunately, research on cyberloafing has not explored whether certain types of people are more likely to cyberloaf (e.g., impulsive individuals, procrastinators). However, Henle and Blanchard did find that males were more likely than females to cyberloaf.

MANAGING CYBERLOAFING

Organizations can manage the occurrence of cyberloafing through three methods: acceptable use policies, monitoring and filtering software, and

organizational sanctions. First, acceptable use policies for Internet and e-mail can be established. These policies should outline who can access the Internet and use e-mail, acceptable uses (e.g., business-related purposes), and sanctions for violations. Companies should also include a statement reserving the right to monitor Internet and e-mail use, which will remove employee expectations of privacy and, in turn, reduce lawsuits alleging invasion of privacy. This policy should be clearly communicated and explained to supervisors and employees, and employees should sign an acknowledgment that they have received, read, and understand the policy. Employers may want to consider allowing some personal use (e.g., before or after work, during breaks) because limited Internet and e-mail use for nonwork purposes may foster learning or creative problem solving, provide a break from stressful or boring work, and help employees balance work and their personal lives.

Next, monitoring and filtering software may be used to track and deter cyberloafing. Monitoring software compiles a report of each Web site visited by an employee, and filtering software blocks access to particular Web pages by keeping a list of inappropriate sites or content. Employers should tell employees why, when, and how they will be monitored. In addition, companies should share Internet usage reports produced by software programs to give feedback on policy compliance and inappropriate Web sites.

Finally, those violating usage policies should be disciplined in a consistent manner. Companies can choose from many different sanctions, including verbal or written warnings, documentation in performance reviews, removal of Internet and e-mail privileges, suspension, termination, or legal action. Some companies take a different approach by providing rehabilitation or counseling services to employees who may have an Internet addiction problem. Several surveys have offered insight into how companies respond to cyberloafing. First, a survey of human resource directors by David Greenfield and Richard Davis indicated that almost 83% have Internet usage policies and about 64% have disciplined and 30% have terminated employees for inappropriate Internet use. Second, the American Management Association found that 60% of surveyed organizations do some form of e-mail

monitoring and 25% have fired employees for e-mail misuse.

SUMMARY

The Internet has changed the way businesses operate by enhancing global communication and information dissemination. Unfortunately, it also offers employees a convenient way of avoiding their job responsibilities. Employers need to recognize that this is a prevalent workplace behavior that can reduce productivity, divert valuable computing resources, and increase security risks and legal liability. The limited research on cyberloafing suggests that employees are more likely to cyberloaf when they perceive mistreatment in the workplace. Companies can reduce the occurrence of cyberloafing through considerate employee relations, acceptable use policies, software, and sanctions. However, organizations should keep in mind that some amount of cyberloafing may be beneficial.

—Christine A. Henle

D

DATA SAMPLING

See SAMPLING TECHNIQUES

DESCRIPTIVE STATISTICS

Measurement provides a means for quantifying important phenomena of interest. In many measurement contexts, researchers are interested solely in efficiently describing the data. Descriptive statistics are the indexes through which such data summarization may be accomplished. Unlike contexts in which the researcher is interested in drawing generalizations from data, descriptive statistics are not used to draw inferences to a larger population.

For example, consider a situation in which a teacher has recently administered an examination. Fundamentally, the teacher has constructed the test in the hope that those with more knowledge of the course material will perform better (receive higher scores) than those with less knowledge of the course material. After scoring the examinations, the teacher records each student's grade in the instructor's grade book, which is organized alphabetically. Although these data can be easily used to identify the performance of any individual student, the alphabetic organization does not provide for easy interpretation of scores as a whole.

One way to use descriptive statistics to make sense of these data would be to construct a frequency table in which scores are rank ordered from largest to smallest along with the number of individuals receiving

each score. This information can also be presented graphically in the form of a frequency distribution in which test score is plotted along the x -axis and frequency is plotted along the y -axis. An examination of such representations of these data can quickly reveal the general shape (e.g., normal, bimodal, skewed) of the distribution of observed scores.

Although graphic representations of data are useful, interpretation of such representations is largely qualitative. Thus, quantitative descriptions are often used to understand the characteristics of a set of data. Frequency distributions are typically quantitatively described along two dimensions: central tendency and variability. *Central tendency* refers to the one score that best captures the center of the observed distribution of scores and can be described by three alternative indexes: mode, median, and mean. Importantly, these values will be identical only when the observed data are normally distributed. As a result, choice of which statistic to interpret should be made based on the scale of measurement and the ultimate use of the data.

Similar to central tendency, variability may be assessed through several statistics, including the range, variance, and standard deviation. The *range* of a set of scores represents the difference between the highest and lowest scores. The *variance* quantifies the magnitude of differences between scores through squared deviations, and the *standard deviation* is computed as the square root of the variance and can be interpreted as an index of variability of individual scores from the mean.

Other descriptive statistics that can be used to describe a set of data quantitatively are skew and kurtosis. *Skew* indicates the extent to which observed

scores occur more frequently at the extreme of the distribution. Positively skewed data are those in which most scores fall at the lower end of the test score scale, and negatively skewed data are characterized by high scores occurring more frequently. *Kurtosis* essentially describes the length of the tails of a frequency distribution. Platykurtic data are those for which the tails are shorter than what would be expected had the data been normal, and leptokurtic data are those for which the tails are longer than would be expected with normally distributed data.

Descriptive data are not confined to use with univariate data. In many cases, for example, there is interest in the extent to which variability associated with one measure is associated with variability in a second measure. As with univariate data, descriptive statistics can be used to both graphically and quantitatively evaluate this question. Graphically, this relationship can be depicted in a joint distribution table or through a scatterplot in which scores for both variables are plotted in two-dimensional space. Because interpretation of these graphic depictions is largely subjective, the correlation coefficient is typically computed as an index that quantifies the observed relationship.

DICTIONARY OF OCCUPATIONAL TITLES

The *Dictionary of Occupational Titles*, or *DOT*, is a comprehensive listing of job titles with accompanying job descriptions, available in a paper format, published by the U.S. Department of Labor. Since its inception in 1939, the DOT has served as an invaluable resource for human resource practitioners in developing job analyses and job descriptions. The latest and final version of

the DOT was published in 1991; the more flexible Occupational Information Network (O*NET) online system is intended to replace the DOT.

HISTORY

In response to the Great Depression, the DOT was first published in 1939 to serve as a resource for business and government to link labor supply with industry needs and thus stimulate the flagging economy. Since that time, the DOT has grown to more than 10,000 entries in its latest (fourth) edition, published in 1991. In recent years, however, there has been a growing recognition that the DOT suffers from a number of drawbacks. First, it cannot be updated quickly in response to changes taking place in today's work organizations. Moreover, its primary focus is on tasks, with relatively little attention paid to what characteristics a worker needs to perform those tasks, and it lacks a common set of descriptors to allow for making comparisons across jobs. Finally, the DOT is not easily accessible because of its paper format. For this reason, the DOT is being replaced by the online O*NET system.

DESCRIPTION OF DOT SUBHEADINGS

Although a range of approaches have been used to develop the DOT listings, the process has typically involved job analysts from the Department of Labor using functional job analysis. Specifically, analysts interview and observe workers and subsequently develop job task descriptions and provide job ratings.

Each DOT listing contains seven components. First, the nine-digit *occupational code number* provides a unique code for each job, classifying the job in terms of occupational category (e.g., professional, technical, or managerial; clerical and sales) and worker functions in terms of data, people, and things. The *occupational title* gives the title of the job in question. The *industry designation* indicates the industry within which the job functions. The *alternate title* provides additional names that can be used for the job in question. The *body* of the listing contains a *lead statement*, which gives a broad description of the job and the activities it comprises; the *task element statements*, which provide a more specific description of the tasks that make up the job; and the list of *may items*, which includes tasks that may or may not be part of this job in different work organizations. The *undefined related titles* are a listing of alternate titles

that may be used in different contexts. Finally, the *definition trailer* designates, via a code, the interest areas involved in the job and the work group and subgroup to which the job belongs; the strength required to do the job; the education needed to do the job; vocational training required; and date of last update.

USE OF THE DOT IN JOB ANALYSIS

The DOT listings are useful for getting a quick thumbnail look at what a job typically involves. In addition, the listings can form an excellent basis for conducting job analyses to be used for selection, training, performance appraisals, and job classification. However, the DOT listings do not provide sufficient detail to serve as job analyses in themselves; their format is too generic and not adapted to specific jobs within individual organizations. Moreover, many of the DOT job analyses are based on the analysis of three or fewer jobs. However, the DOT is best considered a starting point for a job analysis, or one of many sources of job analysis information. It can serve as an invaluable resource for human resource professionals, vocational guidance counselors, curriculum developers, and researchers in academic and organizational contexts.

DIFFERENTIAL ITEM FUNCTIONING

Differential item functioning (DIF) is the preferred psychometric term for what is otherwise known as *item bias*. An item displays DIF when test takers

possessing the same amount of an ability or trait, but belonging to different subgroups, do not share the same likelihood of correctly answering the item. Thus, differentially functioning items elicit different responses from test takers of the same ability level. Because subgroups of test takers are often defined in terms of demographic membership (e.g., sex, race, socioeconomic status), items displaying DIF are sometimes considered “biased” against a particular subgroup. Consider, for example, the items on a standardized test of verbal ability. If the content of one item is sports related, then boys of a particular ability level may have an unfair advantage over girls of that same general verbal ability level. Thus, the item favors boys because it measures a trait other than (or in addition to) verbal ability (in this case, sports knowledge).

It is important to note, however, that the mere presence of item score differences among subgroups does not necessarily indicate the presence of DIF. To return to the example of standardized tests, we would expect 12th-grade examinees to perform better on a verbal ability test than 9th-grade examinees taking the same test. Score differences between these groups would not result because the test is biased against ninth graders, but because of true overall differences in verbal ability. A true between-group difference in ability is referred to as *impact*, which is conceptually distinct from DIF. Complex statistical procedures exist for distinguishing when differences stem from inherent group differences or item bias.

LEVELS OF ANALYSIS

Differential item functioning is a statistical phenomenon that can occur in any item of a test. As DIF accumulates in several items, it can produce differential functioning in clusters of items called *bundles*. The items constituting a bundle may refer to a common reading passage, assess a common skill, share the same grammatical structure, or be of the same item type. This summative effect of DIF is called *DIF amplification*, which allows item-level effects to impact examinee scores at multiple levels of analysis. For instance, prior research on DIF amplification has demonstrated that single items on a history test favoring females yielded a substantially greater advantage when examined together as a bundle. Subgroup differences on such bundles indicate the presence of *differential bundle functioning* (DBF).

In addition, the effects of item-level effects can be examined in all test items simultaneously. *Differential test functioning* (DTF) occurs when test takers of the same ability do not receive the same overall test score. Because modern researchers and practitioners of applied psychology are most often interested in a bottom-line verdict (e.g., does it make sense to compare the results of this employee opinion survey across male and female workers?), greater emphasis is placed on test-level analyses that allow items favoring one group to cancel the DIF of items favoring another group.

DETECTING DIFFERENTIAL ITEM FUNCTIONING

Early approaches to DIF detection relied on analysis of variance (ANOVA) models that treated DIF as an item-by-group interaction and focused on the percentage of examinees responding correctly to each item (p -values). This approach has been criticized as simply an omnibus test of p -value differences, which confound DIF with impact. At present, many DIF detection techniques exist that more effectively operationalize DIF. These techniques can be grouped into those that operate directly on the raw item responses of test takers (nonparametric methods) and those that evaluate the estimated parameters of item-response theory models (parametric methods). Among the more popular nonparametric techniques are the Mantel-Haenszel method, logistic regression procedures, and the simultaneous item bias test (SIBTEST). Popular parametric techniques include Lord's chi-square statistic, the likelihood ratio technique, and the differential functioning of items and tests (DFIT) framework.

DIRTY WORK

Everett Hughes invoked the term *dirty work* in reference to jobs and tasks that are often seen as degrading, disgusting, or debasing. Dirty work is often seen as a necessary evil in society—*someone* needs to clean the streets, save lives in an emergency room, or guard inmates in a prison. Yet, although society acknowledges a need for this dirty work, it stigmatizes the workers who perform it. And because individuals generally define themselves (and are defined by others) at least partly by what they do, those who engage in dirty work are often cast by society and themselves as dirty workers.

DIRTY WORK AS A FORM OF STIGMA

Dirty work is typically thought of as a subset of the larger notion of stigma, which also includes nonwork aspects of an individual or group that reflect some type of taint. Stigma results in a wide variety of psychological predicaments that individuals react to with a diverse set of cognitive, affective, and behavioral coping strategies. Stigma may be experienced at multiple levels, including individual, group, occupational, and organizational. Researchers on stigma often focus on individual differences that bring on stigma, such as physical impairment, unethical behavior, or homosexuality. Occupational research tends to focus on how individuals and groups cope with the stigma brought on by work in specific jobs. Unlike many other sources of stigma, an individual's occupation is seen as controllable. Therefore, society often casts doubt on those who hold dirty work jobs, despite many of the jobs being deemed necessary.

CLASSIFICATIONS OF DIRTY WORK

Multiple classifications of dirty work are found in the literature, including classifying the *sources* of the stigma, documenting the *degree and breadth* of the stigma, and distinguishing between *high and low prestige* types of stigmatized occupations.

Three Sources of Stigma

Early work on occupational stigma by sociologists Erving Goffman and Everett Hughes outlined three

ways that an occupation could be labeled as stigmatized: through physical, social, or moral taint. Although neither Goffman nor Hughes offered exact definitions of these types of stigma, organizational scholars Blake Ashforth and Glen Kreiner gave more specific examples and parameters for each of them. *Physical taint* refers to occupations connected to tangibly offensive things such as dirt, garbage, or death (e.g., embalmers, trash collectors, janitors) or performed under highly noxious or dangerous conditions (e.g., miners, soldiers). *Social taint* refers to occupations involving frequent interaction with stigmatized groups (such as a probation officer's or lawyer's association with criminals) or with markedly servile relationships accepted by society (e.g., taxi driver, butler). *Moral taint* refers to occupations that are regarded by a significant segment of society to be sinful or of dubious virtue (such as exotic dancers, casino workers) or in which deceptive or intrusive methods are commonly employed (e.g., telemarketers, internal affairs officers).

Breadth and Depth of Stigma

Not all dirty work research focuses on extremely tainted jobs. Rather, it has been argued that stigma exists in many jobs, but to varying degrees. Indeed, some degree of stigma can be found in virtually all occupations. One dimension on which dirty work can vary is *breadth of taint*. This depends on (a) the proportion of work that is dirty and/or (b) the centrality of the dirt to the occupational identity. The second dimension on which dirty work can vary is the *depth of taint*. This refers to (a) the intensity of dirtiness and (b) the extent to which a job incumbent is directly involved in the dirt.

Prestige Level of Occupation

As with all occupations, dirty work jobs can be distinguished between relatively low and relatively high prestige. Prestige is generally acknowledged to be a function of variables including status, power, education, and income. Prestige can provide a status shield that protects job incumbents from some of the stigma encountered in lower-prestige occupations. For example, although lawyers, police officers, and prison guards each deal with criminals, their prestige level varies, thus altering the degree to which a social

stigma might stick to them. High prestige offers a fallback cognitive position in the face of pervasive taint from other dimensions of the job.

COPING WITH DIRTY WORK

Ashforth and Kreiner outlined a multipart model that detailed several aspects of coping with the ill effects of dirty work. Each aspect is detailed below.

1. *Strength of occupational culture*. Because of the pervasive influence of societal stigma, and the need to counter its negative effects, dirty work members tend to form work-group or occupational subcultures. Job titles, public visibility, interpersonal interactions, and so forth make the occupation salient. Yet, society is reluctant to confirm positive attributes to dirty work incumbents. So, those in dirty work occupations often create strong subcultures that create an us-versus-them mentality and reinforce positive evaluations of themselves. These strong subcultures then collectively create, reinforce, and provide mechanisms for coping to individuals, as described below.
2. *Social weighting*. Outsiders to a dirty work occupation often are seen as a threat to personal and occupational identity, as they are likely to reinforce the negative stereotypes about the dirty work job. Therefore, those in dirty work jobs often invoke tactics to change the importance of various social groups' perceptions of them.
 - a. *Condemning condemners*. This tactic involves devaluing the perceptions and opinions of those who look down on the dirty workers. By pointing out flaws or shortcomings of those who criticize them, the dirty worker lessens the impact of the criticism. This tactic seeks to decrease the legitimacy of certain outside groups.
 - b. *Supporting supporters*. Similarly, this tactic involves giving additional credence and attention to those individuals and groups who are friendly to the dirty workers (such as friends, family, or workers in similarly stigmatized occupations). By placing greater weight on friendly audiences, the dirty worker can reinforce the positive elements of the appraisal. Note that this tactic increases the legitimacy of certain outside groups.
 - c. *Selective social comparisons*. Social comparison theory is based on the notion that at least part of our self-esteem derives from comparisons we make with other individuals and groups. Highly creative social comparisons have been found in many occupations, and particularly in dirty work

jobs. Social comparisons can occur *within* broad occupational classifications (e.g., a call girl looking down on a streetwalker because of more prestige in her relative position) or *between* occupational classifications (e.g., an exotic dancer feeling superior to her businessmen clients).

3. *Occupational ideology tactics.* Coupled with social weighting techniques are ideological tactics that offer comparatively rosier interpretations of reality. Ideological tactics invoke systems of beliefs that help make sense of the social world and do so in a way that typically benefits the group or individual invoking them.
 - a. *Reframing.* This tactic involves changing the meaning associated with a dirty work job. One way to do this is through *infusing*, which injects positive values into the occupation. This can be done through occupational missions, which describe the purported reason for the occupation's existence. Another way to reframe aspects of an occupation is through *neutralizing*, which deflects or decreases the negative aspects of the occupation.
 - b. *Recalibrating.* This tactic adjusts the criteria that are used to evaluate the dirty work job by either increasing the importance of something others might see as small (e.g., trash collectors saying that society could not function without proper waste removal) or decreasing the importance of something others might see as large (e.g., abortion providers casting abortion as merely one of many women's health services offered by their clinic).
 - c. *Refocusing.* This tactic shifts the attention from the stigmatized aspects of the job to the nonstigmatized aspects. Whereas the other two ideological tactics involve changing the perception of the stigma, refocusing ignores it. This is like the proverbial shell game, in which focus is purposefully diverted from one thing to another. For example, dirty workers could focus on good pay, benefits, flexible hours, or other traditional job design features that are desirable. Key to this tactic, though, is that these positive features (rather than the stigmatized ones) are cast as the *central* components of the job.
4. *Normalization.* The process of normalization takes extraordinary things (events, stimuli, etc.) and transforms them into seemingly ordinary things. The taint of dirty work can be normalized over time through various means, thereby relieving workers of the omnipresent effects of stigma. These means can be employed idiosyncratically by individuals, or become institutionalized over time by organizations

or occupations, and include diffusing, adaptation, and ritualism.

- a. *Diffusing* attempts to dissipate unwanted emotions or to weaken their impact. For example, fear of various dirty stimuli (e.g., insects, heights, blood, dead bodies) can be diffused through humor or shared war stories.
- b. *Adaptation* refers to the process through which reactions to negative stimuli are reduced. This can be achieved through habituation (meaning the stimulus stays the same but a person grows numb to it) or through desensitization (meaning the stimulus is gradually increased to slowly ease the person into change).
- c. *Ritualism* refers to standardized behaviors and techniques that are used to manage anxieties toward negative stimuli. By engaging in ritual, individuals gain a sense of control over otherwise negative situations. Also, rituals create a *momentum of means* that carries individuals through dirty work procedures; this occurs because rituals allow cognitive functions to become routinized such that the negative features of a process are not dealt with at a level of noticeable consciousness.

IMPLICATIONS FOR INDUSTRIAL/ ORGANIZATIONAL PSYCHOLOGY

Key to understanding the management of dirty work is that each of the aforementioned tactics can be invoked purposefully by individuals (workers, supervisors, managers) or by collectives (workgroups, subcultures, occupations, organizations). That is, these processes can be *managed* idiosyncratically, institutionally, or both. Hence, dirty workers have available to them a wide variety of individual and collective tactics to alleviate or change the negative consequences of social stigma. Yet, because of the pervasiveness of stigma, dirty workers face a dilemma of personal identity that is not always solved in either the short or long term.

DISTANCE LEARNING

Distance learning is a method of offsite training in which individuals acquire knowledge and skills via computer. Off-site training methods are those in which the trainee is learning how to perform a job at a place that is removed from the actual job site. Also commonly referred to as *computer-based training*, *computer-assisted instruction*, or *web-based instruction*, distance learning is the most recently developed training method and has experienced significant growth since the advent of the personal computer and the World Wide Web. This growth is projected to continue in the next 10 to 20 years, as people continue to become more comfortable and experienced with the use of computers at home and at work.

DISTANCE LEARNING: SCOPE

Distance learning is a broad topic, and it varies widely on a number of important dimensions. These may include, but are not limited to, the following:

- *Content*. Distance learning has been used to impart a wide variety of material, such as the orientation of new workers, job-specific skills training, personal and career development, management and leadership development, and skills updating and retraining. For example, a leading consumer electronics retailer uses distance learning approaches to teach its regional managers how to give effective feedback to employees and to update its sales representatives on changes to product features.
- *Sophistication*. Distance learning approaches can range from the very simple, such as downloadable learning modules that are text intensive, to the very complex and sophisticated, such as programs in the field of telemedicine, in which users can perform a virtual physical exam on a patient. For example, using a mouse, a medical student could point to an area on a patient's abdomen and then receive immediate feedback on what conditions were discovered.
- *Fidelity*. An effective training environment has high psychological fidelity, in that it closely mirrors the environment in which the trainee will have to perform the actual tasks for which he or she is being trained. For example, a leading worker's compensation insurance company uses distance learning to help its clients' managers to identify and correct unsafe workplace behaviors. Via computer, managers are shown videos of workers engaged in various tasks, such as a package delivery driver lifting a box, and are asked to select the safe and unsafe behaviors that the driver is engaging in. The managers receive feedback on their choices in real time and are offered the opportunity to ask questions and to change their selections.
- *Connection with needs assessment and training evaluation*. The advent of a new training technique such as distance learning does not by itself guarantee a successful training experience. To be maximally effective, a training program has to be guided by a careful needs assessment (and the resultant instructional objectives) and must be thoroughly evaluated on a number of dimensions, such as the amount of behavior change engendered and the eventual impact on the business unit's financial performance. Like more traditional training techniques, distance learning implementations can vary widely with respect to their connection to needs assessment and training evaluation.

DISTANCE LEARNING: ADVANTAGES

Distance learning has many potential benefits both for individual employees and for organizations. Some of these benefits include the following:

- *Individualized instruction*. A well-established benefit of distance learning is that it can provide individualized, personalized guidance to learners, so that learners can often proceed through material at their own pace. Sophisticated systems can adjust the order, speed, and difficulty with which material is presented, and learners can often go back to previously presented material to truly master it.

- *More convenience.* Learners can often interact with the material whenever and wherever is convenient for them, as opposed to having to begin and end a session at predetermined times or places.
- *Lower cost.* Although distance learning approaches often require a sizable initial financial investment, the per-learner cost drops over time as more and more people are enrolled in a program. The result is that most distance learning approaches eventually prove more economical than traditional training methods. Travel expenses associated with training are also substantially reduced.
- *Reduced training time.* Recent studies suggest that distance learning approaches reduce the time expenditure required by training. One study suggests that in contrast to more traditional classroom approaches, distance learning resulted in reductions in training time ranging from 20% to 80%, with 40% to 60% being the most common.
- *Immediate feedback.* Research consistently demonstrates that feedback is most effective when it is immediate, frequent, and specific. Distance learning approaches are especially well suited to delivering feedback of this nature.
- *Improved performance tracking.* Distance learning approaches often have the capability to provide very detailed information about a learner's experience, including the amount of training completed by the learner, the time and speed with which the learner interacted with the material, and the number and type of errors that the learner committed. Although listed here as an advantage, given the contemporary concern with employee privacy and data security issues, the large amount of individually identifiable data that distance learning programs can generate should be handled in accordance with established safeguards.
- *Standardization of training content and delivery.* The majority of distance learning approaches ensure that the same topics are covered in the same way, thereby reducing the possible inconsistencies associated with other training techniques, such as classroom delivery methods.

DISTANCE LEARNING: POTENTIAL ISSUES

Although distance learning has many advantages, it is not without issues to consider. These issues may include the following:

- *Reliance on technology.* Although this is becoming less of an issue because of advances in computer network technology, the success of distance learning programs still depends on the reliability of the technological infrastructure that supports the program.

For example, if a trainee is taking an online posttest to determine the extent to which he or she has learned a segment of material, and the computer freezes or the network connection is dropped, the training experience will be compromised.

- *Individual learner self-efficacy.* People who are uncomfortable with computer technology may be discouraged from enrolling in distance learning programs. This may especially be the case if they have had negative prior experiences with distance learning. As the use of computers becomes more pervasive, issues of comfort and self-efficacy should become less problematic.
- *Lack of adequate research.* In comparison with more traditional training methods, such as on-the-job (OTJ), simulation, classroom, and job rotation, empirical research on the efficacy of distance learning is still in its infancy. Given the increasing popularity of distance learning, there is ample evidence that this paucity of rigorous research is beginning to change, but it still may take time for scholarly consensus to emerge on issues such as Web program development, usability, and the overall efficacy of distance learning programs.
- *Loss of interpersonal contact.* Some participants in distance learning programs report disappointment with the absence of social contact from instructors and colleagues/classmates. Note that the inability to see the trainees may also be problematic from the instructor's perspective. Many organizations attempt to ameliorate this concern by using blended training models, which feature a combination of distance learning and more traditional training approaches. Several organizations and researchers have argued that in comparison to methods that are exclusively distance learning based or that are solely traditional (i.e., conducted in a classroom), these blended models provide superior learning outcomes. Some training practitioners have found it useful to administer a distance learning self-assessment to potential trainees prior to the beginning of a distance learning program. These self-assessments help trainees to decide whether a distance learning format would be a good match for their competencies, needs, and learning style. For example, if an individual reports a low level of comfort with computers, as well as a strong need for interpersonal contact, he or she may not be a strong candidate for distance learning.
- *Distracting environments.* Perhaps the principal advantage of distance learning, its time and geographic flexibility, can also potentially be a pitfall. Classrooms and other set times for training create a physical and psychological separation between training and nontraining time and help to set the

expectation that the trainee is there to focus on the material and to learn. If a trainee is logging on at home, that physical and psychological separation is lost, and the person may be distracted by a variety of home and family demands.

DIVERSITY IN THE WORKPLACE

The term *diversity* refers to all human characteristics that make people different from one another. These differences may be represented by visible characteristics, such as gender, race, ethnic background, and age. However, these differences may also be represented by nonvisible characteristics, such as education,

functional background, organizational tenure, socio-economic background, and personality.

Diversity as a workplace issue was triggered by reports published in the late 1980s indicating that the representation of women and ethnic minorities in the workforce would experience accelerated growth rates in the years ahead. Such changes in the demography of U.S. workforces implied that organizations would be required to change the ways in which people were managed. For example, as the White male demographic decreased in relative size, organizations desiring to attract and retain the highest-quality talent would have to recruit from all demographic categories. Further, because such workforce changes were emerging in an increasingly global economy and marketplace, organizations desiring to remain competitive would have to create strategies for addressing the needs and demands of potential customers from a variety of cultural backgrounds. Organizations also would have to contend with various legal and ethical issues that come with employing more diverse workforces.

Consistent with predictions, the 21st-century workforce is typified by more women and employees with diverse ethnic backgrounds, varied lifestyles, and intergenerational differences than in the past. Such trends are projected to continue, as forecasts show that people entering the workforce in the next 20 years will be more diverse than in the current workforce. Current census projections for the year 2050 are that ethnic minorities will account for almost half of the U.S. population and will soon constitute the majority of new net entrants in the U.S. workforce, particularly because of continued high levels of immigration into the United States. In addition, experts predict that the representation of women and people with disabilities in the workforce as well as the average age of the workforce will increase.

THE CONSEQUENCES OF DIVERSITY

With the increasing focus on diversity in the workplace, there is a growing need for organizations to understand the effects of such diversity. Research generally suggests that diversity can influence employees' attitudes, behavior, and career outcomes, as well as their abilities to interact with others and function effectively in work groups. However, these effects may be both positive and negative.

Diversity brings about differences in people's backgrounds and experiences and, therefore, differences in

perspectives on key issues or problems. Because diverse groups have a broader and richer base of experiences from which to approach a problem, they tend to produce a wider variety of ideas, alternatives, and solutions. In addition, the expression of alternative views in diverse groups may raise the quality of decision making by increasing the group's attention to its decision-making processes. Diversity also increases the cognitive and informational resources available to the group, which enhances critical analysis in decision groups. Because of these different perspectives, diversity tends to result in more creative and higher-quality decisions. In addition, diversity lessens the likelihood of *groupthink*, or the absence of critical thinking caused in part by a group's desire to maintain cohesiveness.

Although diverse groups tend to demonstrate better problem solving, the same diversity that provides for different perspectives may also result in process losses that can limit a group's performance potential. Research shows that whereas similarity on demographic variables increases interpersonal attraction and liking, diversity lessens attraction and open communication between members. Because of lower social integration, members may be less attracted to, and feel less comfortable and satisfied with, the group. Further, diverse groups may be less cohesive and may have higher rates of absenteeism and turnover. Given the increased likelihood of misunderstandings and miscommunication among members of diverse groups, research also demonstrates that diversity is associated with higher levels of conflict. Groups composed of individuals with diverse types of skills, knowledge, abilities, and perspectives tend to experience greater task conflict, or disagreement about the content of the tasks being performed. In addition, differences in members' level of attraction to, and identification with, the group may produce affective conflict, or interpersonal disagreements characterized by anger, distrust, frustration, or other negative attitudes.

Research has also highlighted certain conditions under which diversity is more likely to result in positive than in negative consequences. For example, groups are most likely to reap the benefits of diversity when they are engaged in complex tasks or in problem-solving and decision-making tasks. In addition, the benefits of diversity are likely to occur only after a diverse group has been together for a while. As members learn how to interact effectively with one another, the process losses suffered by heterogeneous

groups diminish. Thus, members of diverse groups must successfully deal with the difficulties arising from diversity before they can reap the benefits. Alternatively, there may be some moderate level of diversity in groups at which barriers to communication and conflict have not fully surfaced and do not supersede the creativity and problem-solving benefits of diversity. The consequences of diversity also may be influenced by the type of diversity that exists in a group, as nonobservable characteristics produce very different effects on group process and performance than do observable attributes. For example, informational diversity, which is likely to arise as a function of differences in education, functional area, or tenure among group members, may stimulate task conflict, which facilitates more thorough analyses and improved decision making.

Diversity in the workplace can be both a liability and an asset. Although the negative effects of diversity may combine to make decision-making more difficult and time-consuming, diverse characteristics and backgrounds may foster higher-quality problem solving, decision making, and performance. Thus, the challenge for organizations is to manage in such a way as to maximize the potential benefits of diversity while minimizing the potential disadvantages.

MANAGING DIVERSITY

The concept of managing diversity refers to efforts by organizations to actively recruit, motivate, retain, and facilitate working relationships among individuals who are demographically different and from a variety of backgrounds. Managing diversity means establishing a heterogeneous workforce to perform to its potential in an equitable work environment where no member or group of members has an advantage or disadvantage. As such, managing diversity differs from affirmative action, which refers to actions taken to overcome the effects of past or present practices, policies, or other barriers to equal employment opportunity. Affirmative action gives managers the opportunity to correct imbalances, injustices, and past mistakes. However, after such inequities are corrected, the long-term challenge becomes to create a work environment that respects and includes differences, recognizing the unique contributions that individuals with many types of differences can make, and that maximizes the potential of all employees and allows them to compete for organizational rewards based on merit.

Diversity Paradigms

Organizations differ in their approaches to diversity management. Some manage diversity with a focus on equal opportunity and fair treatment. Based on an assumption that prejudice has kept members of certain demographic groups out of organizations, this approach is intended to restructure the composition of an organizational workforce to let it more closely reflect the composition of society. Focusing on members of historically disadvantaged groups, this approach concentrates on compliance with federal mandates stemming from equal employment opportunity legislation and affirmative action policies. In addition, organizations following this approach often institute programs to increase the representation of women and ethnic minorities in their workforces and to retain members of these groups in the organization.

Some organizations manage diversity with a focus on access to, and legitimacy in, diverse markets. Under this paradigm, workforce diversity is viewed as a business opportunity. Differences are accepted and valued because they generate a broader range of multicultural competencies and multilingual skills that allow organizations to better understand and serve the needs of customers. As markets become more diverse and minority groups gain purchasing power, organizations also attempt to match the demographics of the workforce with those of customer or constituent groups to gain credibility with such groups. Because differences are believed to enhance an organization's ability to understand and serve its customers, organizations following this approach will institute initiatives to promote and value diversity in the interest of serving niche markets and increasing their market share.

Rather than focus on diversifying workforce composition, some organizations attempt to incorporate employees' perspectives into business processes to leverage the benefits of diversity for organizational effectiveness. This approach incorporates elements of the fairness approach, in that legal compliance is monitored, although methods of compliance beyond those mandated by law are undertaken. This approach also focuses on gaining access to, and legitimacy among, diverse customer groups, although an understanding of such groups is viewed as a learning rather than business opportunity. A learning approach differs from the other approaches in that similarities and differences among employees are seen as meaningful

dimensions of diversity that create both potential advantages and disadvantages and have both short-term and long-term consequences. Diversity provides opportunities for employee perspectives to be incorporated in organizational strategy and processes, with the goal of achieving various strategic objectives, such as efficiency, innovation, social responsibility, or customer satisfaction. Thus, organizations following this approach attempt to link diversity to organizational growth and effectiveness.

Diversity Practices

In response to the changing demographics of the workforce, as well as increased competition, organizations have instituted a variety of programs and practices designed to capitalize on the positive consequences of diversity while minimizing its negative consequences. Many organizations use training and education initiatives to meet the needs and challenges of a more diverse and changing workforce. Such initiatives are considered important for generating sensitivity and awareness for differences in the workplace, imparting an organization's value for diversity to its members, and providing employees with skills and competencies for operating in multicultural environments. Because diversity training is typically used as one of the first measures to introduce the concept of diversity within the organization, it has traditionally been viewed as the key diversity initiative.

The changing demographics of new entrants to the workforce now demand that organizations reconsider their recruitment strategies to understand how to best compete for and attract potential employees. To recruit and retain a more diverse labor force into critical roles, organizations have focused on the image they project to potential job seekers as well as the ways in which they interact with job applicants. Organizations are attempting to diversify their recruitment staffs, as recruiter diversity has been shown to enhance an organization's image as an equal opportunity employer that is committed to diversifying its workforce. Recruitment advertisements are also an important tool in recruiting for diversity, especially given that minority job seekers are more likely to use formal sources of job information and recruitment than are nonminority job seekers. Diverse advertisements are increasingly appearing in mainstream media outlets as well as outlets targeted to specific groups and on the Internet.

Because prejudices and biases that exist outside organizations spill over into workplaces and interfere with the ability of diverse employees to form developmental relationships, organizations have focused on strategies for ensuring that all employees have an equal opportunity to develop their careers. Further, given barriers to the representation of minorities at all levels of organizations and to their participation in social networks, many organizations have also instituted programs to help these individuals to gain both the instrumental and social support resources needed for career success. For example, organizations have instituted mentoring programs to bring together employees at different levels for the purpose of establishing relationships between junior employees and more senior employees, to develop the junior employees' careers. Organizations have also established affinity or network groups, which are groups of similar employees established to facilitate the social and professional support and development of a specific group.

Valuing diversity requires making accommodations for the needs, values, beliefs, and lifestyles that characterize more diverse workforces. Many such accommodations may be required by law to ensure that individuals with disabilities have the opportunity to perform at the level of a comparable person without a disability. However, other key areas of accommodation are currently being made by organizations. Organizations have developed work-life policies and programs to address a broad spectrum of work and personal issues among employees and to help employees balance these responsibilities. For example, family-friendly initiatives, such as family leave and dependent care, are used to ease conflicts between employees' commitments inside and outside of work. Similarly, flexible work arrangements, such as compressed workweeks, flextime, telecommuting, and job sharing, are used to meet employee needs for flexibility. Organizations also provide other types of resources and services to address employees' diverse work and personal issues and to attract and retain a diverse workforce.

DIVERSITY TRAINING

Understanding diversity and its impact on organizational effectiveness has become an organizational priority. This training is no longer perceived as just a part of organizational social responsibility; instead, it is now viewed as a strategic business objective with the capability to make organizations more competitive. More than 50% of all U.S. organizations sponsor some sort of diversity training, at an estimated annual cost of \$10 billion.

Training to improve diversity competency involves a series of programs and activities that reveal similarities and differences among individuals and offer strategies for handling them. However, before any decisions are made concerning the planning and delivery of such training, it is important to define what an organization means by the term *diversity*. Diversity training may be narrowly focused on primary dimensions—characteristics trainees have no control over—such as age, race, ethnicity, and physical ability. Or such training can also include secondary dimensions—characteristics trainees have some control over—such as religious beliefs, marital status, educational level, and geographic location.

Advocates for using a broader definition of diversity identify advantages such as acknowledging the many differences that affect work interactions, making training more agreeable to participants, and reducing trainee resistance. A broader definition also gives trainees greater latitude to discuss issues that are personally relevant to them. Conversely, a narrower definition can prompt trainees to view the training as a corrective action or a program that serves only certain affected groups. Before adopting a definition of diversity, organizations should consider engaging in both an organizational analysis to identify the primary goals of training and an operational analysis to identify the stakeholders and resources necessary to deliver diversity training initiatives effectively.

DIVERSITY TRAINING STRATEGIES

Strategies used in diversity training can be varied and include conceptualization (lecture, readings, film), experimentation (role-playing simulations, guest speakers), experience (immersion in a different group), reflection (journals and diaries), applied activities (team projects), action learning (service activities), and action science (dialogue/discussion, case studies). Many diversity training programs address objectives such as the following:

- Clarifying and addressing trainees' prejudices and stereotypes that promote inaccurate perceptions and attributions
- Helping trainees learn more about others who differ from them and become more aware of the value of diversity
- Showing trainees how to effectively address diversity-related conflicts

Typically, diversity training programs can generally be divided into three broad types: awareness training, skill development, and integrated training.

Awareness Building

Most diversity programs begin with some form of awareness training for employees. These programs strive to sensitize trainees to differing perspectives, values, and norms, as well as interaction patterns that could impede coordination with others from different backgrounds. More pragmatically, these programs seek

to develop communication skills to ensure that interactions are free from prejudicial responses that pose potential legal liability for the organization and thwart the achievement of organizational goals.

Awareness building is designed to increase understanding of the meaning and importance of diversity. Its aim is to reveal unexamined assumptions, biases, and tendencies that stereotype others and how these perceptions affect behaviors, decisions, and judgment. To build awareness, trainees are taught to become familiar with the myths, stereotypes, and cultural differences as well as the organizational barriers that inhibit the full contributions of all employees. This training helps members to be more flexible in their communications with others and to treat each person as an individual rather than rely on a stereotype. In most organizations, the rules for success and advancement are often unwritten and ambiguous. Awareness training offers a means to teach these unwritten rules or cultural values to those who need to know them.

Most organizational diversity training emphasizes the awareness component, and many experts believe that raising trainee awareness is more valuable than skill building. However, these programs rarely address, in a systematic fashion, tactics that enable participants to positively affect diverse work environments. The penchant for awareness training may reflect the greater accessibility of these programs and the tendency to prefer such training because it is relatively inexpensive, easy to conduct, and applicable in a variety of organizational contexts. Although awareness training is a solid first step, and changing values and attitudes are admirable long-term goals, this focus apparently has not resulted in the desired sustainable changes in workplace behavior. Some evidence suggests that awareness programs may perpetuate stereotypes and thus heighten tensions among groups rather than reduce them. Because of these concerns, some practitioners recommend replacing awareness training with a greater emphasis on skill-based training.

Skill Building

Whereas awareness programs target attitudes toward diversity and reveal unexamined assumptions, biases, and stereotypes, skill-based training targets behaviors. Communication is used as the primary strategy for increasing interpersonal effectiveness. Such training teaches employees the practical skills

they need to work effectively in a diverse workplace, such as flexibility and adaptability, negotiation, problem solving, listening across differences, mentoring, and conflict resolution. Some researchers have recommended that diversity training focus only on behavior modification through skill building, not beliefs or awareness.

Integrated Training

A third option for diversity training is to combine the two predominant types in a sequence. That is, awareness training should be presented first and skills training second. This training sequence appears to have wide support. First, awareness training helps employees to understand what diversity means and why it is important. Then skill training provides the specific information and tactics needed for behavior change. Research suggests that a focus on skill training and behavior change may result in later attitude modification.

EFFECTIVENESS OF DIVERSITY TRAINING

Although diversity training has increased, measuring the success of these training programs has been problematic. Reports on the effectiveness of diversity training vary considerably. For example, some research indicates that such training increases knowledge about diversity and support for diversity efforts. Other work, however, has indicated that diversity training is ineffective. Despite this inconsistency, even researchers who acknowledge the potential traps often believe that diversity training remains immensely important and will become even more important in the future.

Diversity training programs rarely are subjected to systematic evaluation. When programs are evaluated, qualitative feedback from trainees is the most prevalent evaluation method. Few organizations measure how employees' behavior is affected by the training. In addition, there has been little work devoted to understanding how trainee characteristics influence training effectiveness.

Motivation to Learn

Because employee buy-in has been identified as an important component of successful training initiatives, organizations should be aware of the potential impact that framing could have on employees'

attitudes toward diversity training. A *frame* is a perceptual lens that directs individuals' attention toward important characteristics of a message. Previous work on framing has demonstrated that it can have a substantial impact on training effectiveness, such that trainees with higher motivation to learn have exhibited posttraining performance superior to that of trainees with lower motivation.

Motivation to learn is the specific desire of the trainee to learn the content of the training program. Significant research confirms that even individuals with the requisite ability will perform poorly in training if their motivation is low and that high motivation to engage in the training program results in more learning. Trainees' motivation to learn influences their decisions about the direction, focus, and level of effort surrounding their participation in a training program. Research has established that training group composition, pretraining experiences, and participants' decision to attend training contribute to participants' motivation to learn.

Training Group Composition

The diversity literature frequently advises organizations to assemble trainee groups that are demographically heterogeneous, particularly concerning the more visible dimensions of diversity, such as gender, race/ethnicity, and age. However, some evidence suggests that heterogeneous training groups may not be necessary or even helpful in all situations. If the organization wants to change on-the-job behavior, and the trainees have previously been exposed to diversity training, homogeneous training groups may be better. However, if the organization wants to change employee attitudes, or if trainees have not been exposed to diversity training, then either heterogeneous or homogeneous training groups may be beneficial.

Diversity Self-Efficacy

Diversity self-efficacy refers to individuals' confidence in their ability to effectively acquire and utilize cognitive and other resources to facilitate appropriate responses to diversity in the workplace. For effective change, diversity training must focus on enhancing self-efficacy and providing the skills needed to affect individual judgments of ability to influence change in themselves and others. A significant body of research supports the claim that self-efficacy is positively

related to training outcomes. Self-efficacy, for example, has been shown to play a significant role in expatriates' ability and willingness to adapt to new cultures effectively.

CONCLUSION

Diversity training has the potential to provide organizations with significant tangible and intangible benefits. However, to realize these benefits, research has offered five suggestions that have been empirically supported:

1. Have strong support from top management.
2. Link training to central organizational goals.
3. Involve all levels of employees.
4. Explicitly address individual behaviors and attitudes.
5. Discuss discrimination as a general process rather than as the experiences of specific groups.

Diversity training is most likely to be successful when it is ongoing or repeated, when there are follow-up activities to see whether the training has accomplished its objectives, and when it is supplemented by other diversity-related activities in an organization.

DOWNSIZING

Downsizing, layoffs, and rightsizing are forms of organizational restructuring. *Organizational restructuring* refers to planned changes in organizational structure that affect the use of people. Organizational restructuring often results in workforce reductions that may be accomplished through mechanisms such as attrition, early retirements, voluntary severance agreements, or layoffs. The term *layoffs* is used sometimes as if it were synonymous with *downsizing*, but *downsizing* is a broad term that can include any number of combinations of reductions in a firm's use of assets—financial (stock or cash), physical (plants and other infrastructure), human, or informational (databases). Layoffs are the same as employment downsizing.

Employment downsizing, in turn, is not the same thing as organizational decline. Downsizing is an intentional, proactive management strategy, whereas decline is an environmental or organizational phenomenon that occurs involuntarily and results in erosion of an organization's resource base. As an example, the advent of digital photography, disposable cameras, and other imaging products signaled a steep decline in the demand for the kind of instant photographic cameras and films that Polaroid had pioneered in the 1940s. On October 12, 2001, Polaroid was forced to declare bankruptcy.

Organizational rightsizing refers to the broad process of aligning a company's staffing levels to the needs of the business, whether it is expanding or contracting. At W. L. Gore and Associates, a contributions-based model is used to ensure that the organization is the right size for its business conditions. Gore employees (called *associates*) work in teams. Team members rank each other using a peer-to-peer contribution-ranking system. The system is based on associates knowing what their coworkers are working on (their commitments), how important this work is to the success of the business (impact of commitments), and what results are being achieved (effectiveness at completing commitments).

Associates who are ranked higher than their counterparts are perceived to be contributing more to the

company's success than those ranked lower. All associates are ranked by their teammates and leaders at least once a year, and the resulting lists place everyone in rank order based on contribution from highest to lowest. The ultimate goal is to develop a contribution-based, rank-order list that is accurate and fair to all parties.

The primary purpose of the contributions-based model is to set pay levels each year. However, it also is used for staffing purposes on an ongoing basis to rightsize the organization. Gore believes that the overall health of the organization will be maintained and improved as associates with high contribution potential are added and those with unacceptably low contribution potential are removed. The process may accelerate in times of major business growth or decline.

The term *resizing* is closely related to the term *rightsizing*. Resizing is the repositioning of an organization's employee ranks to achieve a company's strategic objectives. It does not necessarily suggest massive job cuts. It is primarily strategic in nature, and it is part of an ongoing organizational transformation (as opposed to a one-time-only event). Resizing contributes to executives' intentions to cut costs, focus resources, and implement strategic shifts to capitalize on the ever-changing global marketplace. It typically involves layoffs, divestitures of underperforming assets, and closings of certain operations. Examples include the elimination of jobs at CNN following its merger with AOL Time Warner, United Airlines' closing of money-losing stations, and Vivendi's divestiture of a liquor business that was outside its area of managerial expertise.

An extensive body of research has shown that downsizings, closures, and divestitures often fail to achieve their financial and strategic objectives and that they often produce unintended consequences, such as overwork and stress for those who remain, increases in health care costs for victims and survivors, increases in accidents and workers' compensation claims, and uncertain effects on productivity and profitability. To put this issue into perspective, the next section reviews the extent of downsizing in the 1980s, the 1990s, and the early 21st century.

EXTENT OF DOWNSIZING

An analysis performed for the U.S. Department of Labor examined financial and operating data on 7,194

companies that were listed on the New York or NASDAQ stock exchanges at some point in the 15-year period from 1980 to 1994. Almost a third of the companies downsized 15% or more of their employees at least once during the period of the study. The average magnitude of a downsizing in any given year was about 10%. Manufacturing firms accounted for the largest number of downsizers, service firms were second, and retailers third.

Very large companies, those with more than 10,000 employees, were most likely to downsize employees. This is because they are usually the ones that can take advantage of economies of scale or technological innovation to eliminate redundant workers. In general, employment downsizing is a large-company phenomenon. It occurs commonly among low- and medium-profitability firms. Firms shed workers throughout the 1990s and through 2000 at a rate of roughly 1.5 million per year.

In 2001, however, companies in the United States announced layoffs of almost 2 million workers (1.96 million), with firms such as American Express, Lucent, Hewlett-Packard, and Dell conducting multiple rounds in the same year. Corporations announced 999,000 job cuts between September 11, 2001, and February 1, 2002, alone. In 2003, according to the U.S. Department of Labor's Bureau of Labor Statistics, the United States shed more than 1.2 million jobs, and in 2004, that number declined to just under 1 million. In short, downsizing has become etched into the corporate cultures of many companies, and it is not limited to periods of economic decline.

The phenomenon of layoffs is not limited to the United States. Layoffs occur often in Asia, Australia, and Europe, as well. In western Europe, the incidence of layoffs varies among countries. Labor laws in countries such as Italy, France, Germany, and Spain make it difficult and expensive to dismiss workers. In Germany, for example, all "redundancies" must by law be negotiated in detail by a workers' council, which is a compulsory part of any big German company and often has a say in which workers can be fired. Moreover, setting the terms of severance is uncertain, because the law is vague and German courts often award compensation if workers claim they received inadequate settlements. In France, layoffs are rare. Even if companies offer generous severance settlements to French workers, as both Michelin and Marks & Spencer did, the very announcement of layoffs triggers a political firestorm.

RATIONALE FOR DOWNSIZING

Many firms have downsized and restructured successfully to improve their productivity. They have done so by using employment downsizing as part of a broader business plan. Extensive research has shown that employment downsizing is not a quick fix that will necessarily lead to productivity improvements and improved financial performance. Employment downsizing alone will not repair a business strategy that is fundamentally flawed.

There are at least two circumstances in which employment downsizing may be justified. The first occurs in companies that find themselves saddled with nonperforming assets or consistently unprofitable subsidiaries. They should consider selling them to buyers who can make better use of those assets. Employees associated with those assets or subsidiaries often go with them to the new buyers. The second instance occurs when jobs rely on old technology that is no longer commercially viable. This was the case in the newspaper industry following the advent of computer-based typesetting. There simply was no longer a need for compositors, a trade that had been handed down from generation to generation. However, indiscriminate slash-and-burn tactics, such as across-the-board downsizing of employees, seldom lead to long-term gains in productivity, profits, or stock prices.

THE PSYCHOLOGICAL AND FINANCIAL TOLL

Downsizing is a traumatic event, and it often takes a disturbing toll on workers, their families, and their communities. Lives are turned upside down, people become bitter and angry, and the added emotional and financial pressure can create family problems. *Survivors*, or workers who remain, can be left without loyalty or motivation. Their workplaces are more stressful and political after downsizing. Local economies and services become strained under the impact to the community.

When combined with heavy debt loads, employment downsizings often lead to personal bankruptcies, which hit families hard and ratchet up stress levels. At the same time, employee assistance counselors often report increases in crisis calls involving problems such as online affairs, addictions in adolescents, and spousal abuse.

For those who still have jobs, their incomes, hours, and bonuses are often cut. Money woes also lead to

medical problems, lower productivity, and increased absenteeism and accidents. As for the managers who do the firing, their health suffers, too. A study conducted at 45 American hospitals found that executives ran twice as much risk of a heart attack in the week after firing someone.

GUIDELINES FOR IMPLEMENTATION

If an organization decides that it must downsize, the following principles, based on a considerable body of research and practical lessons born of experience, may prove helpful:

1. *Carefully consider the rationale behind restructuring.* Invest in analysis and consider the impact on those who stay, those who leave, and the ability of the organization to serve its customers.
2. *Consider the virtues of stability.* In many cases, companies can maintain their special efficiencies only if they can give their workers a unique set of skills and a feeling that they belong together. Stability is crucial in knowledge-based and relationship-based businesses.
3. *Seek input from employees.* Before making any final decisions about restructuring, executives should make their concerns known to employees and seek their input. Make special efforts to secure the input of star employees or opinion leaders, for they can help communicate the rationale and strategy of restructuring to their fellow employees and also help to promote trust in the restructuring effort.
4. *Use downsizing or rightsizing as an opportunity to address long-term problems.* Unless severe overstaffing is part of a long-term problem, consider alternatives to layoffs first, and ensure that managers at all levels share the pain and participate in any sacrifices employees are asked to bear.
5. *Be mindful of fairness and consistency.* If layoffs are necessary, be sure that employees perceive the process of selecting excess positions as fair and make decisions in a consistent manner. Make special efforts to retain the best performers, and provide maximum advance notice to terminated employees. Provide as much personal choice to affected employees as possible.
6. *Communicate regularly and in a variety of ways in order to keep everyone abreast of new developments and information.* Executives should be visible, active participants in this process, and lower-level

managers should be trained to address the concerns of victims as well as survivors.

7. *Give survivors a reason to stay and prospective new hires a reason to join.* Be able to explain how business processes will change and why the organization will be better able to compete and to serve its customers after downsizing. Alternatively, a stable, predictable employment relationship is a powerful attraction to join and to stay at an organization.
8. *Train employees and their managers in the new ways of operating.* Evidence indicates that firms whose training budgets increase following a restructuring are more likely to realize improved productivity, profits, and quality.
9. *Examine carefully all management systems in light of the change of strategy or environment facing the firm.* These include workforce planning, recruitment and selection, performance management, compensation, and labor relations.

DRUG AND ALCOHOL TESTING

Organizations use drug and alcohol testing to determine whether an employee (or prospective employee) is under the influence of alcohol or specific drugs. The drugs included in the test are illegal drugs such as cocaine, marijuana, PCP, and methamphetamines and commonly abused legal drugs such as amphetamines, barbiturates, and opiates.

Drug and alcohol tests are also used to confirm that employees are in compliance with organizational substance abuse policies. Many organizations are drug-free workplaces. They have policies and programs that prohibit drug and alcohol use in the workplace. Testing is used to ensure compliance with their policy.

The primary reasons employers use testing are safety and productivity. A variety of statistics connect employee alcohol and drug use with higher absenteeism, lower productivity, higher medical insurance claims, and increased frequency of on-the-job accidents and injuries. Evidence also connects increased employee theft, property damage, and security issues to workplace drug use. All of these represent significant costs to organizations that can be reduced by preventing drug and alcohol abuse among employees.

There are legal reasons to conduct drug and alcohol testing. Many employers are required under state or federal regulations to have policies prohibiting drug use among employees. These laws are often justified under the umbrella of public safety. For example, truck drivers and railroad workers are covered by Department of Transportation regulations that require drug and alcohol testing.

Employers who choose to implement a drug and alcohol testing program typically analyze the costs and benefits of the program. Employers argue that the benefits of preventing drug and alcohol abuse significantly outweigh the costs of a testing program. Preventing one serious accident is usually enough to justify the cost of the program. In the case of government-mandated testing, the cost of testing is considered a normal cost of business.

Drug testing programs are intended to affect the behavior of applicants and employees. Many employers advertise their testing program to job applicants to deter current drug users from applying or being hired. By educating current employees about the testing program, employers hope to discourage employees from using prohibited drugs or abusing alcohol.

Testing identifies potential policy violations. Organizations can then remove the offenders from the workplace or put them into a rehabilitation program. In many programs, the testing policies explicitly encourage employees who may have chemical dependency problems to seek appropriate treatment. Treatment or counseling options may be offered in lieu of disciplinary action.

Many employers offer an employee assistance program (EAP) that provides free and confidential counseling to employees and their immediate family members. An EAP allows employees to get professional help with drug or alcohol problems before getting caught in a testing program.

Employers also use testing to reduce potential liability. For example, if an employee's drug or alcohol use could cause harm or injury, the organization may use testing to reduce that risk. In the event of on-the-job accidents, testing may identify a contributing cause of the accident. Under workers' compensation law in some states, a positive drug test may reduce or eliminate the employer's financial liability for a work-related injury.

TESTING METHODS

Several methods are used to test employees for drug use:

- *Urine test:* The most common test is a urine test. Urine samples are easy to collect and cost-effective to test. The disadvantage of urine testing is that a variety of substances and equipment are available for the sole purpose of cheating on the test.
- *Blood test:* Blood tests for drugs are more accurate than urine tests. It would be virtually impossible to cheat on a blood test. However, a blood test is considered by many to be invasive and is considerably more expensive than a urine test.
- *Hair test:* Hair retains detectable residue of drugs. The hair test is considered to be very accurate. It does not necessarily prove that someone was under the influence at the time of the test. The hair sample test is expensive. Although not invasive, hair sample testing is not common. It would, however, be difficult to cheat on a hair test if the sample were collected properly.
- *Sweat test:* A relatively new test uses a sweat sample. The individual wears a patch on his or her skin for several days. The patch collects a sample of sweat, which is then analyzed for the chemical residue and active ingredients of various drugs. The patch cannot

be reattached if it is removed, therefore limiting tampering or cheating.

- *Saliva test:* Saliva can be tested for both drugs and alcohol. This test is accurate, samples for it are easy to collect, and cheating on the test is difficult, but it is not currently a common testing method.
- *Alcohol test:* Testing for alcohol levels is usually performed by one of two methods: a breathalyzer test or a blood test. Both tests are considered accurate and are difficult to dispute when done properly.

A positive test is one in which the presence of drugs or alcohol is detected and confirmed above a defined threshold level. Threshold levels are carefully set to prevent false positives or positives owing to incidental exposure. A negative test is one in which no prohibited substance is detected in the sample above the threshold levels. A negative test does not conclusively determine that the individual is not a drug user. It only verifies that at the time of the test, the person was not considered under the influence.

TESTING PROTOCOLS

For all tests, it is critical that specific protocols are followed to maintain integrity in the process. For tests mandated by federal law, the federal regulations require specific procedures. For any program, applicable state and federal laws should be reviewed prior to developing the program. To avoid challenges to test results, it is extremely important for employers and testing facilities to strictly follow all required protocols. Some typical protocols are described below.

Samples must be obtained under controlled conditions to limit opportunities for tampering or cheating. For example, when a urine specimen is collected, the toilet used should have dyed water in both the bowl and the tank to prevent sample dilution. Fresh water should not be available in the room where the sample is collected. The temperature of the specimen must be checked to verify there was no substitution or dilution.

Samples must follow a strict chain-of-custody process. The chain of custody documents who handled the specimen and the times and dates of every change in custody. The custody documentation must be retained with each specimen. This ensures the sample is not tampered with at any step in the process.

Tests should be done only by certified labs that have proven they meet or exceed all applicable regulations, levels of accuracy, and staff competence.

Equipment should be tested regularly with known samples. Positive results must be verified using alternative testing equipment to ensure accuracy.

The laboratory must have a medical review officer (MRO) review all positive tests. The primary responsibility of the MRO is to receive, review, and interpret all test results before they are reported to the employer. The MRO would answer any questions regarding the accuracy of the test. The MRO must be a qualified licensed physician.

TYPES OF ALCOHOL AND DRUG TESTING

Employer testing programs typically include the following types of drug and/or alcohol testing:

- *Preemployment:* Testing done on job applicants prior to hire. Preemployment testing is normally done after a contingent job offer is extended. The offer can be rescinded if the applicant tests positive. Applicants sign an acknowledgment that they are aware of the preemployment testing requirements and that any job offer is contingent on passing a drug test.
- *Random:* Testing that is done on an unscheduled basis. Employee drug testing can occur at any time to anyone covered by the program. This approach adds an element of surprise and would presumably discourage drug use. Random testing programs select a specified number of employee names for testing at regular intervals.
- *Postaccident:* Testing that is done immediately following any work-related accident. The policy should describe specifically what conditions trigger a test—for example, requiring a test after any accident that involves a personal injury or property damage.
- *Reasonable suspicion:* Provides for an employee to be tested if there is reason to believe that the employee is under the influence or unfit for duty. Those with the authority to require a test must be trained to recognize what would justify reasonable suspicion. Difficulty walking, talking, or performing simple tasks; smells of alcohol or marijuana; or witnesses who observed use of prohibited substances are examples of behaviors and circumstances that might trigger a reasonable suspicion test.
- *Scheduled:* This is testing conducted at regular or scheduled intervals. It is common in industries that for safety or security reasons test employees on a regular basis. It is also used for follow-up testing as part of last-chance agreements. In those cases, the employee has previously tested positive and as a condition of employment is subject to ongoing tests.

- *Baseline:* Testing done at the start or implementation of a drug program. Employers can use baseline testing to identify drug users and then either terminate them or provide substance abuse counseling.

ARGUMENTS AGAINST DRUG AND ALCOHOL TESTING

Workplace drug and alcohol programs are criticized for a variety of reasons. Common arguments are based on invasion of employee privacy and accusations of inaccurate tests resulting in false positives.

The invasion of privacy argument is based on the premise that employers should not have the right to dictate off-work behavior, particularly behavior that does not affect the employer. This argument is easier to accept for off-duty behavior that clearly has no connection to work performance or the employer. In some situations, employees' off-duty activities and affiliations may even be protected by law. For example, under federal law employees cannot be discriminated against based on their religion or union membership.

However, in the case of drugs or alcohol, an employer would argue that a test showing the active ingredients of illegal drugs or the presence of alcohol over a certain limit does affect the person on the job. In the case of dangerous jobs, this can be a very compelling argument. Employers carefully word their policies to prohibit employees from being under the *influence* of drugs or alcohol at work. The presence of the prohibited substances in the employee's blood or urine while working would therefore be a violation of company policy. It would not matter where or when the drug or alcohol was ingested. The employer has an interest in the employee's off-duty behavior because it affects on-duty behavior and job performance.

OTHER ISSUES AND CONCERNS

Recently, local and state laws have been proposed—and, in some jurisdictions, have passed—that legalize the use of marijuana for medical reasons. The Supreme Court has ruled that local laws do not supersede federal laws or regulations regarding the use of marijuana. This has allowed employers to continue to treat marijuana as an illegal substance even in areas where its use is legal under certain circumstances.

Because drug testing involves personal medical information, the use and release of test results may fall

under federal privacy laws. Most employer policies already treat drug testing information as private and highly confidential. Employers should be even more careful in today's legal environment to ensure that strict confidentiality is maintained.

Training is key to the successful implementation of any drug testing program. Employees need to be aware of how the program works and to have some level of confidence in the process. Employee education about the effects of drugs and alcohol in the workplace is also critical to acceptance of the program. Managers need to be trained in how to recognize signs of drug use. At the same time, they must be cautioned against making a diagnosis. That should be left to trained professionals.

Cheating on drug tests is a serious concern; however, it is hard to measure. Numerous Web sites and other resources claim to offer proven methods or products for beating drug tests. Product offerings include clean urine specimens, masking agents, and even prosthetic devices to deliver a clean sample while under observation. As long as there are drug users, there will be a market for ways to cheat. It is important for employers to be aware of cheating methods and to design procedures that minimize the opportunity for cheating.

Employers can expect periodic claims that a result was a false positive. The usual allegation is that something other than inappropriate drug use caused a positive result. In most cases, the threshold level set

for a positive result will virtually eliminate false positives for secondary or dietary exposures to similar substances. The issue of addressing allegations of a false positive test is best left to the MRO. This person is well qualified to determine if there is any possibility of an inaccurate result.

Drug and alcohol testing is very complex. Laws vary from state to state. The technology for testing has dramatically changed over time. In addition, the ingenuity of cheaters continuously improves. An employer implementing a testing program should obtain competent technical, medical, and legal advice.

E

ELECTRONIC HUMAN RESOURCES MANAGEMENT

Electronic human resources management (eHR) focuses on the use of technology to maintain employee records and enhance human resources (HR) processes, including job analysis, recruitment, selection, training, performance management, and compensation. There has been an increased use of eHR systems in recent years because they are thought to (a) streamline HR processes, (b) reduce cycle times, (c) increase efficiency, (d) decrease costs, and (e) enhance the degree to which organizations can attract, motivate, and retain talented employees.

IMPACT OF TECHNOLOGY ON HR PROCESSES

The use of technology has prompted a number of changes in HR processes. Selected examples are described in the following paragraphs.

E-Job Analysis

Organizations can now access job descriptions online and collect data for job analysis from employees and supervisors via sophisticated online questionnaires (e.g., Common Metric Questionnaire). Data from these systems are automatically summarized, and standardized job descriptions are created. In addition, many of these systems convert the data to a job evaluation format and create job evaluation point scores for use in compensation systems.

E-Recruiting

To attract talented applicants, a large number of organizations now use Web-based systems, portals, or kiosks to post job openings and screen résumés. These e-recruiting systems are also used to track applicants, provide them with virtual job previews, and evaluate the cost and effectiveness of recruiting strategies. Research on e-recruiting systems has shown they do attract a larger number of applicants but may not always attract higher quality applicants than traditional sources. In addition, research suggests that the perceived ease of use and navigability of a Web site may affect applicants' motivation to apply for jobs, but the attractiveness of the Web site may not always influence applicants' attraction to organizations. Furthermore, research has indicated there are individual differences in the use of e-recruiting systems. For example, research has shown that online recruiting is more likely to be used by young, male, well-educated, computer-literate applicants than by those who are women, over age 55, or lack computer skills. In addition, research has revealed that White candidates may be more likely to use online systems than some ethnic minorities (e.g., Hispanic Americans). One reason for this is that there is a digital divide in society that precludes some ethnic minorities from gaining access to computers or receiving computer training. However, other studies have shown that African Americans may be receptive to online systems, especially when they perceive these systems to be objective or as providing them with information about the climate for minorities in the organization. Taken together, these findings suggest that the use of e-recruiting may affect the characteristics and diversity of an organization's workforce.

E-Selection

Organizations are now using e-selection systems to assess job applicants' knowledge, skills, and abilities; manage applicant flow; and evaluate the effectiveness of selection systems. For example, résumé scanning systems often search résumés for keywords and provide candidates with immediate feedback about whether they are qualified for jobs. In addition, organizations now conduct interviews, personality assessments, and background checks online and use computerized testing to examine candidates' cognitive ability levels. Furthermore, intelligent Web-based systems are used to generate profiles of applicants' strengths and weaknesses, and can be used to generate a set of specific interview questions for managers. The data from these systems are then combined with results of drug tests and other assessments to help managers make final hiring decisions. Little research has been conducted on e-selection, but some critics have argued that online systems (e.g., cognitive ability testing, keyword systems) may not produce reliable and valid assessments because they are not always monitored or based on job analysis. It merits noting that e-assessments are subject to the same professional standards as other selection procedures.

E-Learning

Organizations now use various forms of technology, including Web-based systems, CD-ROMs, audio- or videoconferencing, and audio- or videotapes, to design and enhance the delivery of education and training programs. The use of technology also means that education and training systems can be delivered to remote locations (i.e., distance learning), which may increase the flexibility and decrease the overall costs of training. Research on distance learning shows it can be a viable method for training in workplace skills but is best used to convey hard skills (i.e., explicit knowledge) rather than soft skills (e.g., interpersonal skills). Furthermore, some research shows that most employees prefer face-to-face instruction to distance learning. As a result, researchers have argued that organizations might use blended or combined face-to-face and e-learning techniques to meet employees' needs. In addition, researchers contend that organizations should consider the following factors when designing e-learning systems: (a) human cognitive processes needed, (b) trainees' degree of

control, and (c) strategies for engaging trainees in the learning process.

E-Performance Management

Technology contributes to performance management in three primary ways. First, it can facilitate the measurement of performance through computer monitoring. For example, computerized systems can be used to count (a) the number of work units completed per time period, (b) the number of keystrokes, (c) time spent on various tasks, or (d) error rates. Second, technology may be used to facilitate the process of writing appraisals and for delivering feedback to employees (e.g., multirater appraisal systems). Third, technology can track unit performance, absenteeism, grievance rates, and turnover levels over time. Research on e-performance management has shown that these systems have both functional and dysfunctional consequences. For example, some research shows that computer-mediated feedback is often more accurate and honest than face-to-face feedback, and these systems may increase the frequency and timeliness of feedback. However, e-performance management systems may also create distance between supervisors and subordinates, which can decrease trust and negatively affect attitudes, productivity, and turnover rates. Similarly, these systems may result in a reductionist approach to management, which is analogous to computerized scientific management.

E-Compensation

Web-based software tools are increasingly being used to help organizations administer compensation, benefits, and payroll systems. In particular, technology assists with the management of compensation systems by (a) providing managers with a tool to design and model the costs of compensations systems, (b) giving organizations access to critical labor market data that will help them maintain a competitive edge in the labor market, (c) providing employees with information about benefits, (d) providing self-service systems that allow employees to select or change benefits, (e) streamlining burdensome payroll processes, and (f) enabling organizations to comply with extant laws and union contracts. Although there has been little empirical research on e-compensation systems, researchers have argued that these systems have a number of benefits. For example, they can be used to

ensure that compensation systems are equitable and may enhance employee motivation and retention levels. However, other researchers contend that these systems may decrease the service provided to employees and managers by the HR department and may actually shift work from the HR department to employees.

FUNCTIONAL AND DYSFUNCTIONAL CONSEQUENCES OF USING eHR

Given the increased use of technology in human resources management, it is important to consider the functional and dysfunctional consequences of using these systems to meet HR systems goals. First, eHR systems should be aligned with the organization's mission and enable the organization to attract, select, and retain employees who have high levels of motivation and job-related skills and abilities. Second, although these systems may streamline processes and reduce cycle time in organizations, they may also decrease flexibility and depersonalize HR processes. Some research shows that online communication systems are viewed as less beneficial than face-to-face communication because they are less interactive and weaken personal relationships. As a result, organizations should consider the extent to which eHR systems provide service to employees and managers and affect their overall satisfaction levels. Third, in designing eHR systems, organizations should consider the degree to which individuals accept these systems. For example, it has been suggested that eHR systems are more likely to be accepted in Western cultures (e.g., western Europe or the United States) than in Asian or Latin American cultures, because they are predicated on Western HR practices and cultural values. Fourth and finally, organizations should consider the degree to which eHR systems have the potential to invade personal privacy. In particular, it is important that organizations develop fair information policies that ensure employee data are accurate and place limits on the extent to which data about individuals can be disseminated to third parties.

ELECTRONIC PERFORMANCE MONITORING

Electronic performance monitoring describes the process of obtaining information about work-related behaviors using various forms of information technology. The information may simply be observed behaviors but can also take the form of measurements of time, resource usage, an individual's or a vehicle's movement through space, or various combinations of these. Electronic monitoring of employees is often conducted on behalf of their supervisors, ostensibly in service of improving productivity and quality, but may also be conducted for other purposes in an organization (e.g., for the maintenance of information security). Technology can monitor groups of people, but it is most typical to monitor the activities of individual workers.

Decreasing costs and increasing capabilities of information technology have provided one impetus for the increasing use of electronic performance monitoring in organizations. This increasing use has caused both researchers and managers to give greater attention to the issues surrounding this application of technology. Historically, nontechnological performance monitoring was performed by an employee's supervisor, who personally recorded and reported the worker's performance and behavior. Many of the questions that have arisen around the uses of electronic monitoring relate to the ease, simplicity, and inexpensiveness of delving deeply into the myriad detailed on-the-job activities of workers. Questions have arisen about whether electronic monitoring may sometimes constitute an invasion of workers' privacy and whether intensive monitoring may have adverse health effects on workers.

The remainder of this entry includes consideration of two issues. First, a brief history of monitoring and monitoring technology sets the stage for a description of current practices. Second, a concise exposition on the implications of monitoring describes issues for practitioners and for future researchers.

ELECTRONIC MONITORING TECHNIQUES

The use of electronic performance monitoring in business settings actually predates the use of computers. In one of the first widespread deployments of electronic technology, the Bell Telephone Company began the

use of manual telephone switchboards in the 1870s. The first operators of these switchboards were teenage boys, presumably because of the low labor costs and wide availability of such workers. Unfortunately, the teenagers frequently spoke rudely to callers and, as a result, were soon replaced by young women, who proved more reliable and courteous. In urban telephone switchboard offices, young women were soon directing hundreds of calls per hour. Bell Company managers had learned from their earlier experiences, however, and were keenly interested in ensuring that the young women consistently treated callers courteously even under the strain of handling many calls per minute. One technique the managers used to accomplish this supervision was to listen in on a sample of calls completed by the operators. As the technology behind the telephone switching system became more sophisticated, the managers also obtained the means to time each call transaction, ascertain the average speed at which an operator was handling calls, and calculate the time an operator spent on rest breaks and other “nonproductive” activities. By the early to mid-1900s, telephone operators were one of the most closely monitored groups of workers in history; it was the technological nature of their jobs that made this monitoring economical for companies. The cost of the monitoring technology was more than offset by the managers’ ability to identify low-performing operators and either motivate them to perform better or remove them from the workforce.

Meanwhile, researchers in Bell Telephone’s laboratories were busy creating new technology to enhance the telephone system and make it more reliable. Some of this research culminated in the development of the transistor in 1947, which in turn shortly led to the mass commercialization of digital computers. Within about 15 years, a completely new class of highly monitored workers emerged—data entry clerks and computer operators. Beginning with IBM’s marketing of the model 360 computer in 1964, many large companies started to use mainframe computers as an essential part of their operations. With this usage came a continuing need to transform paper records into electronic records, a tedious and repetitive process that was once again performed mainly by women. Because data entry by its nature is a computer-based activity, the use of electronic performance monitoring was quite straightforward from the start. Data entry software automatically counted keystrokes and completed records. Using these records, the software

also calculated each clerk’s speed, break time, and overall productivity. As with telephone operator monitoring, these records helped managers to differentiate between high- and low-performing clerks and take personnel actions based on a desire to obtain the highest possible productivity from each worker.

As the 20th century ended, the increasing sophistication and power of digital computers gradually reduced the need for workers to perform repetitive, manual tasks using computers and other electronic technologies. For example, caller dialing, automatic call switching, and touch-tone menu systems have largely eliminated the need for the great majority of telephone operator jobs. Image scanners and optical character recognition have likewise greatly decreased the need for data entry clerks. Note, however, that these trends apply mainly in developed countries: In underdeveloped countries, the use of manual labor for automatable tasks is still substantial. In addition, global trends in outsourcing have moved many low-skill clerical tasks from locations where they could have been automated—at some substantial expense—to locations where the labor costs are still so low that it is more cost-efficient to have humans do the work. In some countries with low labor costs and large English-speaking populations, for example, it is still highly common to have human operators who handle high volumes of customer service and support calls. In these situations, the use of electronic performance monitoring as a means for measuring and controlling the quantity and quality of task completion is also still common.

Setting aside these carryovers of the older electronic performance monitoring techniques, the most common application of electronic monitoring in contemporary organizations is to track and control the behavior of information systems’ users. Unlike the earlier applications of electronic monitoring, which tended to focus almost exclusively on task completion rates and related measures of individual productivity, these new applications of electronic monitoring are deployed much more frequently in the service of information protection. The telephone operators and data entry clerks of old have been replaced by a new class of knowledge workers whose productivity depends not on the repetitive completion of mundane tasks, but rather on the timely compilation, manipulation, and distribution of information. The tasks these workers undertake are too complex and unpredictable to be counted or measured in the tick-tock fashion of

operators and clerks, but electronic monitoring has proved nonetheless valuable for their managers. In the contemporary information-driven business, the value of electronic monitoring comes from the value of the information that the organization maintains in its information systems. Databases, services, applications, and all of the other facilities that information workers use to get their jobs done must be protected, and electronic monitoring of employees' computer usage is one of the key tools in this protection regime.

Various technologies help to monitor who did what, where, and when everywhere within an organization's information systems. Computer operating systems ensure that each time a user retrieves, modifies, or deletes a piece of information, a record is made of the fact. Logs of computer activity show who worked on files, how long they spent working on them, and the extent of the changes made to the information. Most database systems contain auditing capabilities that provide administrators with an ongoing record of who has done what to the data. These measures help control access to valuable organizational information and prevent its corruption or destruction. Although these records can also certainly provide data on an employee's level of productivity, a more common problem in this time of Internet-connected laptops and desktops is nonproductive activity.

Connecting an organization's internal computer network to the Internet has obvious benefits for many companies but also has the potential to substantially disrupt operations in two major ways. First, the Internet provides an avenue for malicious software and individuals to gain access to the company's internal network. Second, the Internet provides a method for employees to conduct non-work-oriented activities with relative ease and without leaving the building. Unfortunately, the latter problem often facilitates the former problem, because recreational computer activities such as peer-to-peer file sharing and instant messaging also create substantial opportunities for malicious outside agents to gain access to and destroy internal information. As a result, many firms that have Internet access also extensively monitor their employees' use of that access. In particular, e-mail and browser usage are two of the most commonly monitored Internet activities.

At the most basic level, companies often keep a record of who sent messages to whom: sender and recipient addresses. At the next level, companies may keep complete records of the contents of messages

because these are sometimes needed for legal or regulatory purposes. Finally, developments in automatic text processing (also known as *natural language processing*) have also made it relatively straightforward and inexpensive to actively analyze message content—a capability that is frequently used to detect unauthorized distribution of intellectual property or inappropriate uses of company e-mail systems. Detecting inappropriate usage is also a primary function of the Web tracking and filtering programs used by many companies. Web tracking and filtering programs stand as a gateway between each employee's computer and the Internet at large and therefore are able to compile reports of all of the places employees have visited with their browsers. These systems often show that employees use their workplace computers for nonbusiness Internet activities such as shopping, reading the news, downloading music, and viewing pornography.

In addition to these computer and Internet monitoring techniques, a variety of related technologies are beginning to mature for tracking the movement of people and material in time and space. For example, many truck drivers are now electronically monitored through Global Positioning System devices that pinpoint the location of a vehicle from moment to moment, combined with satellite-based digital communications for relaying the location information to a central office. On a smaller scale, many firms have begun to use active badges, radio frequency identification tags, and digital video surveillance to monitor the movement of people and products within the confines of their facilities. Like many other monitoring techniques, these positioning and tracking systems help to maintain security and protect the organization's assets.

In short, like many technologies, electronic monitoring has made a major transition from its pre-Internet days to the present. Whereas most of the early applications of electronic monitoring focused on aspects of job performance such as productivity rates and transaction quality, in contemporary organizations, electronic monitoring is at least as likely to be used as a tool to protect the organization and its resources. With this transition, the character of the jobs affected by electronic monitoring has also changed. Whereas older forms of monitoring tended to focus on routine, repetitive jobs in which workers—mainly young and mainly women—were closely watched by managers, modern forms of electronic monitoring are used to track the activities of anyone

and everyone, regardless of their position in the corporate hierarchy. Although it is most straightforward and inexpensive to monitor the digital activities of computer users, it has also become increasingly feasible to monitor what workers do in the physical world.

IMPLICATIONS OF ELECTRONIC MONITORING

The shift from monitoring worker productivity to monitoring all computer activity has also resulted in a change in the focus of researcher and practitioner activities related to monitoring. In 1987, the now defunct United States Congressional Office of Technology Assessment published a comprehensive report of the accumulated research on electronic monitoring of worker productivity. The summary of this report referred to concerns about labor conditions, worker health, stress, the opposition of labor unions to the use of monitoring, and a host of related issues. The emphasis of this report on how monitoring was used to enforce difficult productivity standards and restrictions on break time perfectly matched the primary focus of monitoring on measuring and increasing productivity in repetitive work. Although some researchers continue to refine the research findings in this area, it is largely accepted that the way in which productivity monitoring is deployed within an organization has a substantial effect on worker health and stress. Several different researchers used the term *electronic sweatshop* to refer to the monitored work environment, and although not all call centers and data entry firms could be fairly categorized as such, the overall body of research has made a reasonably convincing case that extensive and harsh usage of monitoring can indeed adversely affect worker health and job-related attitudes.

Fast-forward to the present, and it is evident that the focus of concern about electronic monitoring has changed substantially. Electronic monitoring now affects the majority of white-collar workers, assuming those workers are employed in organizational environments that use networking technology and computers. These organizations generally do not use the monitoring to enforce difficult productivity standards, and thus the effects of monitoring on worker health, if present at all, are likely to be much more subtle and indirect. Instead, the major concern that has arisen pertains to privacy and expectations about nonproductive workplace behavior.

Norms, laws, and regulations pertaining to worker privacy vary substantially from country to country and from region to region. For example, in the United States, workers generally enjoy few legal- or regulatory-based privacy protections on the job, whereas in the European Union, such protections are much more extensive. Despite the lack of protections, however, workers often have concerns about privacy in the workplace, and some of those concerns relate to electronic monitoring. In organizations where equipment exists for monitoring phone calls, e-mails, instant messages, and Web activity, it can become difficult for workers to make routine contacts to family members or conduct everyday nonbusiness tasks that are generally permitted to white-collar workers. In certain sectors—such as national security—such extensive controls may be warranted, but within a typical organization, both managers and workers often see the value of providing some kind of protected space where employees can conduct non-business-related activities without concerns for personal privacy.

As a result, one of the current major research and practice challenges in the area of electronic monitoring is establishing the organizational conditions and processes that will lead to a balance between the organization's right to protect its valuable resources and workers' rights to occasional use of workplace computers, the Internet, and other organizational assets for legal nonbusiness activities. Like earlier research on electronic monitoring—which required cross-disciplinary knowledge of divergent areas such as stress and software design—this new direction for research requires a combination of disciplinary approaches. For example, industrial and organizational psychologists can combine their knowledge of human behavior, cognition, and emotion to assist those with expertise in information systems and information security. Using a combination of these different areas of expertise, researchers and practitioners can address the challenges of implementing a powerful array of electronic monitoring technologies while protecting each worker's right to a measured degree of seclusion, autonomy, and control in the workplace—in short, a limited right to workplace privacy. Overcoming these challenges will in turn require an understanding of how to use training, organizational communications, and other techniques to establish an atmosphere of trust that will enable worker acceptance of reasonable and appropriate monitoring techniques.

SUMMARY

In more than a century of usage, electronic monitoring has evolved from a technologically primitive workplace activity focused on maintaining worker productivity into a sophisticated collection of tools for examining and controlling the computer-related behavior of employees. With this shift, the concerns expressed about the impacts of electronic monitoring have also shifted. Whereas early concerns pertained to the use of monitoring to enforce difficult productivity standards, the contemporary concern revolves around the intervision of the electronic eye into every corner of the modern, computer-enabled workplace. To avoid misuse of electronic monitoring, managers must balance an organization's need to protect its valuable resources—for example, information and information services—with basic needs and rights of those employees who are subject to electronic monitoring. Addressing the research and practice challenges involved in this balancing act will require expertise from those who study and understand people, as well as those who study and understand technology.

EMOTIONAL BURNOUT

Burnout is a set of negative human reactions to prolonged experienced stress on the job, especially reactions to exposure to stressors in the social environment at work. The burnout itself is also prolonged or chronic in the sense that it tends to last over a period rather than be an acute, short-term reaction. Furthermore, it might take different forms over time. Burnout is concerned with both the well-being of the individual and the success of the person in performing on the job, just as many other important topics in industrial and organizational psychology are.

As with most topics in work psychology, workers themselves certainly recognized the phenomenon of burnout before scholarly researchers did, but in the case of burnout, the term was even coined in the more popular press before it became a topic of serious study and practice. Researchers first theorized and studied burnout among people with human service careers—for example, psychotherapists and social workers. In fact, the early work on burnout defined its cause as working with and helping people in need. Subsequently, however, perhaps because the term *burnout* was so engaging, it became common to consider that people in any type of job can experience burnout.

It is difficult to discuss research on burnout without considering its measurement. More than most other major topics in industrial/organizational psychology, the theoretical construct of burnout has almost become synonymous with one specific questionnaire measuring it, the Maslach Burnout Inventory (MBI). Paraphrasing from a comment on definitions of job satisfaction, one could almost say that *burnout* is defined as whatever the MBI measures. This measure of burnout, and/or its separate subscales, is so widely used that the comments in this entry often concern both the construct and this particular measure of it.

FACETS OF BURNOUT

The MBI's original three subscales measure the three dimensions of burnout assumed to encompass the phenomenon: emotional exhaustion, depersonalization, and (reduced) personal accomplishment. *Emotional exhaustion* is often acknowledged as the core of burnout and is pretty much what the label implies: a feeling of tiredness, lack of energy, and

generally negative and inactive emotion. Emotional exhaustion is frequently used by itself in research, sometimes with the label of *burnout* but other times being called *emotional exhaustion* or given even more general labels. Burnout is often considered to be distress or strain in the language of job stress literature—that is, it is seen as a harmful, aversive reaction resulting from environmental stressors. The centrality of the emotional exhaustion facet of burnout is probably the main reason for this view, because conceptually and empirically it resembles psychological strains in that literature. One difference is said to be that burnout, or just the emotional exhaustion facet, is job-related, whereas psychological strains such as depression are not necessarily job-related. This is an issue in which the measurement of burnout and the construct influence each other; the overwhelming majority of questionnaire items, for example, refer to something about workplace (job, work, clients, etc.). That is, most of the emotional exhaustion items tend to ask if people are emotionally exhausted at work or because of work. It seems possible that if the workplace were not referenced in the measure, the measure would appear and act even more as general depression-type items do.

Reduced personal accomplishment is a feeling that one does not or even cannot do good and important work on the job. On the MBI in particular, this dimension has been renamed in recent years as a *sense of inefficacy*, and some of the items measuring it do indeed resemble work-related self-efficacy items.

Depersonalization refers to the phenomenon in which human service workers go beyond the frequently recommended professional objectivity about their clients to the point where they think of clients more as objects than as humans, and they actually care about their clients less. This depersonalization might stem from the psychological burden of constantly working with people who have problems that are difficult to solve. Depersonalization could even be a way of attempting to cope with this type of job. Although depersonalization can technically occur only for people whose jobs require working with clients of some sort, the concept of burnout intuitively applied to other types of jobs, as well, and in recent years a new version of the MBI was developed that is intended for use with jobs in general (not necessarily human services jobs); it has a subscale labeled *cynicism* instead of the depersonalization subscale. Thus, for non-human services jobs, burnout might consist of emotional exhaustion, feelings of inefficacy, and

cynicism. Work-related cynicism has not been studied widely in industrial/organizational psychology, and therefore this measurement and conceptual development cannot easily be set in a context of related industrial/organizational psychology research topics. *Cynicism's* basic meaning in English is a lack of belief in the virtue of other people. In the workplace, this might mean lack of faith or trust in the intentions and abilities of people to do good or appropriate things; therefore, its use to replace the people-oriented construct of depersonalization for non-human services jobs appears logical. The items in the MBI measure of cynicism do not directly address this concept, however; instead, most of them tend to ask about more general negative views of work such as psychological engagement with it. Because research on burnout relies so heavily on this questionnaire, the literature on employee cynicism will surely burgeon in the near future. Whether or not it actually will address cynicism is uncertain, however, given that the items may not address cynicism very clearly.

A great deal of research has been conducted on burnout, especially with the original MBI, and the three subscales (emotional exhaustion, depersonalization, and feelings of inefficacy) tend to be factorial independent of each other, showing they probably are indeed separable constructs. In addition, a meta-analysis showed that emotional exhaustion and depersonalization tend to be strongly correlated with each other but not with feelings of inefficacy. There have been hypotheses that these three burnout reactions develop separately or at least at different times. One proposition is that emotional exhaustion develops first, depersonalization second, and inefficacy last. A second is that depersonalization develops first, inefficacy second, and emotional exhaustion last. A third is that emotional exhaustion and inefficacy develop first and at the same time, and then depersonalization develops last. Most research does not actually measure burnout as it develops, however, and the facets' developmental order, if any, is uncertain. Some rationales for these orderings depict depersonalization as a kind of coping attempt, the idea being that depersonalizing clients is a way of reducing the emotional pain that can come from caring too much about people experiencing problems. One type of rationale is that depersonalization comes late in the process as a way to alleviate human service providers from the pain arising from the other two facets of burnout. Conservation of resources theory has become a somewhat

popular explanation for burnout in recent years, and it takes the position that depersonalization serves this purpose; it conserves the energy and effectiveness of the person. Alternatively, however, depersonalization might come earlier in the process but makes people feel they are no longer faithfully doing the good and important work they had set out to do early in their careers, leading to feelings of inefficacy or even emotional exhaustion.

POTENTIAL CAUSES AND CONSEQUENCES OF BURNOUT

There are many potential causes and consequences of burnout. Most of the research has used cross-sectional and nonexperimental methods, however, and as a result, there is little strong evidence about these. Potential causes prominently include occupational stressors, such as role overload, role ambiguity, and role conflict. In occupational stress theory, these stressors are derived from role theory and represent expectations or demands that the people in a role place on the focal person. Thus, these stressors have an interpersonal component. Other stressors, such as pressure for performance and a variety of stressful events, might also lead to greater burnout. Unmet expectations are also related to burnout, and this is consistent with the idea that burnout develops over time in a job. The perception of an inequitable work environment might also lead to burnout, although this relationship might not be linear or simple. Some environmental characteristics also might lead to *lower* burnout, including innovative environments, jobs using the person's valued skills, participation in decision making, and job autonomy. The empirical evidence for these and for the other relationships reported here tend to be more consistent for emotional exhaustion and depersonalization than for inefficacy, however.

In addition to the work environment, some personal characteristics or individual differences also appear to predict burnout. These include both demographic and dispositional variables. The empirical relationships found between environmental predictors and burnout are much stronger and more consistent than relationships between personal factors and burnout, but it should be remembered that the measures of the environmental factors are nearly always the person's perceptions of the environment rather than objective measures. To the extent that age is related to burnout, the relationship appears to be negative, with younger

people reporting more burnout than older ones. It could be predicted that older people would be more burned out owing to their longer experience with the occupation, but the negative relationship is usually interpreted as meaning that older people were different in some way—so that they survived instead of burning out and leaving their jobs. That is, those who burned out when they were younger left the job and are no longer there to be detected by burnout studies when they are older. The relationship between other demographic variables and burnout is even less clear, but women and single people might have slightly higher levels of burnout. Regarding personality or dispositions, evidence for causation is not strong, but people who have generally “good” or healthy characteristics tend to report less burnout. These characteristics include internal locus of control, low neuroticism, high self-esteem, hardiness, and type B behavior pattern.

Although burnout can be considered an outcome of stress and therefore important in its own right, another reason to be concerned about it is that it might lead to other important outcomes. Outcomes from burnout would be expected to include distress or strains (or other strains, if burnout itself is a strain), low organizational commitment and job satisfaction, few organizational citizenship behaviors, low job performance and low career success, high absenteeism, and high turnover. Obviously, some of these outcomes would be important to an employer. Less research has been done in this area, and therefore there is less certainty about the relationships with potential outcomes. One would expect the different facets of burnout to be related differentially to each outcome. For example, emotional exhaustion should be related especially to other strains or ill psychological or even physical health, inefficacy should be related to lower job performance and career success, and depersonalization might be more closely related to fewer helping behaviors that are part of organizational citizenship toward individuals. There is some modest evidence for this, but more striking is the overall finding that emotional exhaustion and depersonalization tend to be related to other variables in general more strongly than inefficacy is.

REMAINING ISSUES FOR PRESENT AND FUTURE

Coming back to the issue of measurement, it is not wholly certain whether there might be more or different facets (or even fewer) of burnout than the three in

the MBI. Very quickly in the early research on burnout, this measure became the standard, perhaps because it was relatively successful in tapping an intuitively important problem, was easy to use, and gave good results to researchers. It has been a very serviceable instrument for researchers and practitioners alike. We can make the definition of *burnout* isomorphic with this measure, and burnout will, by definition, have these three facets. The changing of one facet from depersonalization to cynicism (for non-human services jobs) indicates that the three may not be set in stone, and there have been a few limited research attempts to add other facets, as well. This might be an issue for future theoretical and empirical work.

There has been a great deal of interest in burnout, especially in the helping professions, and this has resulted in many efforts to reduce it, often in the form of workshops and self-help books. There have been far more efforts toward application than toward evaluating the effectiveness of the applications, however. Most interventions focus on changing the person in some way, rather than changing the presumed cause (the environment), and many are relatively short in duration. The very short (e.g., one half or even one whole day) workshops might not be very effective, but there is more promise when the interventions are long term and include periodic booster or follow-up sessions. Very gradually, more and better empirical evaluations are occurring, and we will eventually learn more about the effectiveness of interventions aimed at reducing burnout.

EMOTIONAL INTELLIGENCE

Emotional intelligence (EI) is the ability to reason with, and about, emotions. This is the ability model of emotional intelligence developed by psychologists Peter Salovey and John Mayer in 1990. However, since that time, emotional intelligence has come to mean many different things to both the public and to researchers. Some popular approaches to emotional intelligence (also referred to as EQ, for *emotional quotient*) view emotional intelligence as a set of personality traits or as a set of traditional leadership competencies. The result has been a good deal of confusion, as models and assessments that have little or no basis in either emotions or intelligence employ the EI or EQ terminology. Emotional intelligence defined as traits or competencies does not appear to offer anything new, whereas EI defined as an ability may or may not represent a new construct.

The term *emotional intelligence* had been used in an unsystematic way in the 1980s and earlier, but it became widely known in 1995 through the publication of a trade book titled *Emotional Intelligence: Why It Can Matter More Than IQ*, written by Daniel Goleman, a psychologist and science writer for the *New York Times*. The book became a best-selling publication. It described a loose collection of skills and traits as emotional intelligence, thus permitting a wide range of preexisting models, assessments, and approaches to be relabeled to include the term *emotional intelligence*. Even researchers began to base their work on this trade book, rather than examining the intelligence-based roots of the construct.

DEFINITIONS OF EMOTIONAL INTELLIGENCE

Emotional intelligence can be defined as a set of personality traits, as competencies, or as an intelligence.

Trait-based approaches gather together traits such as optimism, assertiveness, and reality testing to create an EQ construct. Competency-based approaches include traditional leadership competencies such as influence, communication, and self-awareness. The ability-based approach to EI posits four related abilities: identifying emotions accurately; using emotions to facilitate thinking; understanding emotional causes and progressions; and managing emotions to result in optimal outcomes.

WHAT AN EMOTIONAL INTELLIGENCE SHOULD LOOK LIKE

Approaches to emotional intelligence can best be evaluated by looking at the two parts of the construct: emotions and intelligence.

Intelligence and Emotional Intelligence

Intelligence has been defined in a number of ways, such as the ability to think abstractly, to reason, and to adapt to environmental demands. The existence of a general mental ability factor (*g*) does not preclude the possible existence of other intelligences, such as spatial or emotional, and the importance of more specialized abilities has also been recognized by *g* theorists such as John Carroll. Evidence as to what sort of intelligence an emotional intelligence might be is very limited, but there is a suggestion that it might be best viewed as a crystallized rather than a fluid intelligence.

Emotion and Emotional Intelligence

An emotional intelligence must be based on the processing of emotions or emotional information. Emotions are complex and likely involve a number of processes, including cognition, arousal, motor activity, and action tendencies. Emotions are signals, primarily about interpersonal events and relationships. Emotions can also be differentiated from moods: emotions are more specific and goal-oriented than are moods. An emotional intelligence should address the processing and management of both moods and emotions.

Evaluating Models of Emotional Intelligence

There is no agreed-on definition of emotional intelligence, but it seems clear that an acceptable scientific

definition must position emotional intelligence as a form of standard intelligence that operates on, and/or with, emotional information.

MEASUREMENT OF EMOTIONAL INTELLIGENCE

Measures of EI can be placed in a three-by-three matrix: how EI is defined (trait, competency, or ability model) and the measurement method used. It can be measured via a traditional self-report survey (“I tune in to people’s emotions”), a competency 360 (“George tunes in to people’s emotions”), or an ability test (“Indicate what emotions are expressed by this face”). Common tests include the Bar-On EQ-i (a self-report trait EI measure), the Emotional Competency Inventory (ECI, a 360 competency measure), and the Mayer, Salovey, Caruso Emotional Intelligence Test (MSCEIT, an ability measure of ability EI). Generally speaking, self-report measures of trait-based EI do not appear to substantially differ from traditional personality measures (e.g., Big 5 measures), and self-report measures of ability EI are generally unrelated to ability measures of ability EI.

The major difficulty with ability-based EI measures such as the MSCEIT is how to determine the correct answers to the emotional problems. Consider an item on the “faces” task of the MSCEIT: a photo of a person’s face. The test taker rates the face on the presence of a number of discrete emotions. Several methods have been attempted for scoring such an item, including target scoring (agreement with the person expressing the emotion), general consensus (agreement with a large sample of test takers), and expert consensus (agreement with a sample of emotions experts). Although expert and general consensus scores tend to converge, suggesting that there are right answers to such test items, the absence of true, veridical scoring criteria remains a limitation of the ability approach to measuring EI.

PREDICTIVE VALIDITY OF EMOTIONAL INTELLIGENCE

One of the many popular appeals of emotional intelligence was the claim that it was “twice as important as IQ.” However, the actual claim was that emotional intelligence, defined loosely, was a better predictor than was analytical intelligence (IQ) for certain “soft” outcomes such as relationship quality. In reality, EI as a trait shows little discriminant validity above and beyond traditional

personality variables. Emotional intelligence as an ability, controlling for IQ and Big Five traits, has some predictive validity. Ability EI appears to be predictive of the quality of interpersonal relationships and, inversely, of the frequency of negative behaviors.

Findings for ability EI in the workplace are not robust, but there is a suggestion that ability EI has some predictive power for a limited range of performance “how” outcomes as opposed to performance “what” outcomes. Some of these outcomes relate to quality of vision statements, team support networks, and team-oriented leadership styles.

TRAINING OF EMOTIONAL INTELLIGENCE

Trait- and competency-based EI training programs have been developed, with participants demonstrating significant pretest–posttest differences. However, these evaluations are based on self-report EI measures and may simply reflect expectation bias. To date, there is no evidence that supports the contention that ability EI can be increased. Indeed, if EI is viewed as a standard intelligence, then it is unlikely that a training intervention, especially a short-term one, would demonstrate an impact on measured EI.

SUMMARY

The trait-based and competency-based approaches to emotional intelligence are nothing new. However, once the overblown popular claims for an emotional intelligence are critically examined, we conclude that emotional intelligence, defined as a standard intelligence, is a construct separate from general cognitive ability or dispositional personality traits (e.g., Big 5), can be measured reliably, and is modestly predictive of a narrow range of important life outcomes.

EMOTIONAL LABOR

Emotional labor is the regulation of felt and expressed emotions at work in the service of organizational goals. The construct of emotional labor is traced to the seminal work of sociologist Arlie Hochschild, who studied the work of airline flight attendants and, specifically, the strategic use of emotion by flight attendants to create a desired experience for passengers. Her research revealed that the work role of flight attendants involved much more than the obvious duties of serving drinks and meals and ensuring passenger safety and comfort. Their job role also included the expression of emotions and the creation of feeling states in others; they were required to act friendly and upbeat to make passengers feel safe, happy, and comfortable. The significance of this early work is that it highlighted the fact that the management of emotions is an important organizational phenomenon, it is an effortful process for employees, and it may affect employee well-being.

Jobs that require emotional labor typically are those that (a) involve direct contact with the public, (b) require the employee to use emotions to produce an emotional state in another person, and (c) allow the organization to exert some control over the felt and/or displayed emotions of employees. Customer service jobs are those most typically associated with high demands for emotional labor. Service employees spend a great deal of time interacting with the public. Part of their job is to produce an emotional state such as happiness or delight in the customer, because with services, much of what the customer is evaluating is intangible. As such, the customer’s affective experience becomes part of his or her evaluation of the organization and its product. Finally, the organization exerts some control over the customer service agent’s emotional display. Employees are often trained on the types of emotions to display, and this behavior is enforced by peers, management, and customers.

Emotional labor is relevant, however, to many jobs that fall outside typical ideas of service work, and not

all emotional labor is the management and display of positive emotions. Bill collectors and police detectives manage and display negative emotions to produce anxiety, fear, and compliance in debtors and suspects. Funeral directors display warmth and sadness in their job roles. And physicians engage in emotional labor by suppressing negative emotions to display the neutrality required of their jobs. In all of the above cases, the employee ultimately is managing his or her displayed emotions: expressive behavior including, but not limited to, facial expressions, vocalizations, and posture. This expressive behavior communicates important information to the receiver and can be viewed as a control move, an intentional means of manipulating the situation to produce a desired response in the receiver. Emotional labor is, as such, a tool of influence: it is intended to produce responses in others that are favorable to the individual and/or the organization.

THE PROCESS OF EMOTIONAL LABOR

Display Rules

Because displayed emotions are an important component of many jobs, *display rules* are created to serve organizational and professional goals. Display rules are norms about which emotions are appropriate to express in a particular job or organization. Flight attendants, for example, learn the importance of expressing good cheer even to rude passengers. Scholars also have described organizational *feeling rules*, or norms about the emotions a person is supposed to feel in a given situation. Salespersons for Mary Kay cosmetics, for example, are taught not just to display good cheer but that it is important to *feel* enthusiastic about their products. Most current emotional labor research focuses on display rules, as norms in service organizations typically specify the emotions one is supposed to display publicly. Whether the norms are about expressed or felt emotions, however, it is the existence of display rules that makes emotional labor necessary.

Surface Acting and Deep Acting

To display the emotions required by organizational display rules, employees may engage in one of two processes: surface acting or deep acting. *Surface acting* involves faking or “painting on” the appropriate emotion without any change in corresponding internal

feelings. A busy waiter who smiles despite the rage he feels at a rude customer is engaging in surface acting. In deep acting, the employees induce the required emotions in themselves, such that the expressed emotion is not fake, but is a true emotion that has been created to serve an organizational end. Bill collectors, for example, may take a moment to create in themselves a slight feeling of anger or annoyance before placing a phone call, so that they can more naturally express urgency and irritation toward the person on the other end of the phone.

Because emotional labor is fundamentally a process of emotion regulation, recent theoretical work now frames surface and deep acting within the broader framework of emotion regulation. Emotions can be regulated by two processes. *Antecedent-focused* emotion regulation acts on emotion-eliciting stimuli before they can produce a full emotional response. An example of antecedent-focused coping is cognitive reappraisal: thinking about the situation differently so that it does not produce undesired emotions. Physicians engage in cognitive reappraisal when they cognitively transform patients from real people into analytic and clinical objects to ward off any inappropriate feelings that might interfere with their required neutral affective displays. Antecedent-focused coping is analogous to deep acting. Emotions also can be regulated through *response-focused* coping. Response-focused coping works only on changing the outward expression of emotion, not the experience of emotion. Suppressing the display of negative emotions in the face is an example of response-focused coping and is analogous to surface acting.

ANTECEDENTS OF EMOTIONAL LABOR

Conceptualizing emotional labor as the regulation of emotion to conform to organizational display rules, the antecedents of emotional labor, or those things leading to greater or lesser degrees of emotion regulation, can be thought of broadly in terms of (a) situational and contextual demands on displayed emotions, or (b) factors that influence an individual’s felt emotions.

Situational Demands

Certain jobs have more demanding emotional labor requirements than others: the clerk at an exclusive boutique likely has more intense display rules than does the cashier in a discount chain store. Organizations

develop and maintain display rule norms through recruitment and selection, socialization, and rewards and punishment. Research on Disney's theme parks reveals intense recruitment and socialization, including formal training, on many issues pertaining to emotional displays, including smiling and proper greeting of park guests. Reward and punishment is common in, for example, the use of secret shoppers who record employee smiles and demeanor.

Situational demands also come from the nature of interactions with customers. In jobs where interactions with customers are more frequent, are of longer duration, and require a greater variety of emotions to be displayed, the demands for regulating emotions will be stronger. Direct customer demands also influence the need to regulate emotion. Some research suggests that customer social cues, including gender, enhance emotional labor demands (males appear to receive more positive emotional displays than females). The pace of the work environment also affects demands for the regulation of emotion. Research has consistently shown that as store busyness (in terms of customers being served) increases, the display of positive emotion decreases. It appears that during busy times, norms emphasize speed and efficiency and deemphasize the display of positive emotions during interactions with customers. It seems likely that during busy times, employees also feel greater stress and negative emotion, which would make emotion regulation more difficult.

Felt Emotions

Perhaps not surprisingly, employees are not always successful in regulating their emotional displays. Despite efforts to conceal them, real feelings do leak out and can be perceived by others. This is particularly true when employees engage in surface acting without changing true, underlying affect. Therefore, employees who experience higher levels of emotions that are incongruent with display rules will find it necessary to engage in greater emotional labor. An important caveat to this statement is that this is only true to the degree that employees are committed to organizational display rules.

Felt emotions are also influenced by affective events in the workplace that influence employee positive or negative emotion. If these events produce emotional states that are incongruent with display rules, more emotion regulation will be required. Store

busyness, with its potential to create negative affect, and an interaction with a rude customer are two examples of negative affective events.

OUTCOMES OF EMOTIONAL LABOR

Effects on Employees

A major premise of the early work on emotional labor was that it can have a detrimental impact on employee well-being. When there is a discrepancy between felt emotions and displayed emotions, a state of *emotional dissonance* is proposed to exist, and, theoretically, this is a stress-inducing state. Individuals who report engaging in surface acting should be, in theory, experiencing emotional dissonance, because they report changing the expression of emotion but not the underlying affect.

In general, evidence for the existence of emotional dissonance and the negative effects of emotional labor is mixed. Laboratory research clearly shows that suppressing the expression of felt negative emotion has detrimental effects on physiological and cognitive functioning. Further, emotional labor is a type of self-regulation, and ample evidence demonstrates that self-regulation is an effortful process that can divert cognitive resources from other tasks. Therefore, it is logical to suspect that emotional labor taxes cognitive resources and could potentially hinder performance in other domains. For example, a bank teller who is focused on maintaining a positive emotional display would be expected to make more errors, and laboratory research on emotional labor appears to support this position. The generalizability of this research, however—particularly the social psychological research on general emotion regulation—to field settings where employees are frequently called on to amplify positive emotions (in addition to suppressing negative ones) has been questioned.

Several studies have demonstrated links between emotional labor demands and stress outcomes, yet frequently these studies are based on self-reports, and recent research suggests that, across several studies, no consistent differences in stress outcomes have been found in individuals in “people work” jobs (those with higher emotional labor demands) than in other jobs. Additionally, several studies have found associations among surface acting, stress outcomes, and the display of positive emotions as reported by observers. Although promising, this research has yet to establish

that the negative effects associated with surface acting result from emotional dissonance per se.

In sum, it is clear that emotion regulation in the service of organizational goals can, in some cases, tax cognitive and coping resources. On the other hand, research also suggests that over time, some emotional labor may become routine and automatic, requiring little effort. Surface acting is associated with negative outcomes for employees, but no research has convincingly demonstrated that emotional dissonance, or the discrepancy between felt and displayed emotions, is the cause of these negative outcomes. This is perhaps the most fruitful area at this moment for future research on emotional labor.

Finally, emotional labor also can produce positive outcomes for employees. Emotional labor is a control move ultimately designed to influence others. Successful emotional labor may give employees feelings of competence and mastery in their ability to control the emotions of a situation. It likely contributes to successful job performance and financial gains—for example, when the salesperson successfully uses emotions to generate excitement and purchases from a client.

Outcomes for Customers and Organizations

Because customers evaluate a service as an experience, the display of positive, integrative emotions by employees can lead customers to more positive evaluations of the service and organization. Customer mood may also be affected directly (and perhaps outside of conscious awareness) by the process of emotional contagion. *Emotional contagion* is the process of mimicking and synchronizing emotional expressions between interaction partners. As a result, interaction partners converge emotionally: One person can “catch” the affect of the other. Research has shown that customers interacting with employees expressing positive emotions find themselves in a better mood and subsequently evaluate the organization’s services more positively. Emotional contagion processes have also been shown within teams and between leaders and followers.

SUMMARY

Emotions were, at one time, viewed as the antithesis of rationality in organizations; they were viewed as a

distraction that should be minimized. Today, there is awareness that emotions are important and can serve useful organizational ends. Emotional labor, the regulation of felt and expressed emotion by employees, is an effortful, learned process. Emotional labor, like any behavior that taxes resources, may have some detrimental effects on employee stress and well-being. The nature and role of emotional dissonance in causing these detrimental effects remains unclear.

EMOTIONS

In 1884, William James asked the fundamental question about the nature of emotions in his famous article “What Is an Emotion?” More than 120 years later, psychologists still wrestle with this question, and a single, precise definition has proven elusive. Definitional precision has been difficult both because *emotion* is a word lifted from common language—it is not a scientific term—and because scientists studying emotion approach it from many different perspectives. Psychologists from evolutionary, cognitive, and physiological traditions each focus on different antecedents, components, and outcomes of emotions. Further, an emotion is not one thing; it is a cluster of responses.

DEFINING EMOTION

In light of these obstacles to a precise definition, however, most researchers agree that emotions have the following characteristics. First, they include a subjective, experiential feeling state. This is the prototypical idea of an emotion: It is what we commonly refer to as *feelings* and what psychologists call *affect*. Second, emotions include a physiological component. Anger, for example, is associated with autonomic changes in areas such as heart rate and galvanic skin response. Third, emotions have a behavioral component. This includes expressive behavior as seen in facial and postural changes, and action tendencies (e.g., the tendency to recoil when experiencing fear). Finally, most definitions of emotion also include an evaluative component connecting the emotion to a specific person, object, or event. That is, emotions have a focus: We are angry *at* someone or sad *about* something.

It is this final component that is useful for distinguishing emotion from the closely related concept of mood. *Moods* are affective states, similar to the subjective, experiential feeling state of emotions. Moods also typically are of a longer duration, and are less intense, than emotions. But the primary feature that distinguishes emotions from moods is that unlike emotions, moods lack a specific focus. Moods are broad and diffuse, whereas emotions are associated with a person, object, or event that has been evaluated as significant for the individual. In distinguishing emotions from related concepts, it is useful to think in terms of a hierarchy, with affect, the subjective feeling state, as a broader, higher order category characteristic of both emotions and moods. If the affective state is accompanied by distinct physiological changes, behavioral tendencies, and a referent person, object, or event, it is most appropriate to classify it as an emotion.

Because *emotion* is a term lifted from common language, its use, even in the scientific literature, does not always match the definition provided here. Concepts such as emotion regulation, emotional contagion, and emotional labor often focus more on general affective states than on emotions per se. Thus, more technically correct terms might be *affective regulation*, *mood contagion*, or *affective labor*. For most uses of these concepts, however, the distinction between affect and emotion is relatively unimportant, and because these terms are well established in the literature, their use will continue.

DISCRETE EMOTIONS VERSUS DIMENSIONS

There are two traditions in psychology for how to best conceptualize emotions. In one camp are those who argue for the existence of a small set (5 to 9) of discrete primary emotions. These typically include happiness, interest, surprise, fear, anger, sadness, and disgust. Evidence for the existence of basic emotions is mostly drawn from studies showing the existence of distinct, specific, and universal (across cultures) emotional antecedents and responses. Particularly influential in this area is the work of Paul Ekman, whose research has demonstrated the existence of a small number of distinct, universal facial expressions of emotion. Across numerous cultures (Western and Eastern, modern and premodern), basic emotions such as fear are expressed in the face in the same manner and are universally recognized in pictures of facial expression. There have, however, been several influential critiques of the entire notion of basic emotions in recent years.

In contrast to the basic emotions view is the view held by researchers who assert that the domain of affective experience (mood and emotion) can be described by two underlying dimensions. Typically, one dimension is described as *valence* or *hedonic tone* (from pleasant to unpleasant), and the other dimension is *intensity* or *arousal* (from high to low). The structure of affective experience can then be described by a model called the *affective circumplex*. The affective circumplex is represented as a circle created by two bisecting dimensions: valence and arousal. All emotions can be represented as falling in a circle around these dimensions, as each can be described by different levels of valence and arousal. Anger is a combination of negative valence and high arousal; sadness is negative valence at moderate levels of arousal; boredom is negative valence at low levels of arousal. There is a vigorous debate surrounding how to best use the circumplex to represent affective experience. One group of researchers argues that affective experience is best represented by the orthogonal dimensions of positive and negative affect (each dimension representing a combination of valence and arousal), whereas others argue that the dimensions of valence and arousal best represent affective experience (see the May 1999 issue of the *Journal of Personality and Social Psychology* for a special section devoted to this debate). Despite this ongoing debate, virtually all researchers studying emotions from a dimensional perspective use the circumplex model in some form.

In industrial/organizational (I/O) psychology, most researchers have adopted a dimensional view of emotions. This is seen in, for example, the wide use of the Positive and Negative Affect Schedule (PANAS) measure, which is based on the affective circumplex. The prevalence of the dimensional view in I/O psychology research likely stems from the fact that it allows researchers to move seamlessly between discussing general affect, mood, and emotion. The dimensional perspective also meshes well with research on personality: Research shows links between positive and negative affect and, respectively, the Big Five dimensions of extraversion and neuroticism. Further, many outcomes of interest in I/O psychology—for example, prosocial organizational behavior—are sufficiently broad that they are likely better predicted by general categories of emotion than by specific, discrete emotions. Critics of the dimensional view of emotions have argued, however, that conceptualizing emotions in terms of two general dimensions masks important differences between discrete emotions. Anger and fear, for example, are both emotions characterized by high arousal and negative valence. The dimensional view treats these emotions as similar, yet they have unique antecedents and outcomes. As such, in certain areas of study (for example, abusive supervision, in which employees may be expected to experience anger, fear, or both), theoretical precision may warrant the study of discrete emotions.

INDIVIDUAL DIFFERENCES IN THE EXPERIENCE AND EXPRESSION OF EMOTION

Individuals differ in the quantity and quality of emotions they experience and express. How these differences emerge can be conceptualized by using an input-output model of an individual's emotional experience. The experience of emotion begins with an emotional stimulus, such as an interaction with an angry customer. The input triggers *emotion-response tendencies*, the behavioral, physiological, and experiential changes that represent the initial experience of emotion for the individual. Certain individuals (e.g., those high in the personality trait of neuroticism) will be more sensitive to these negative stimuli than others, producing stronger response tendencies in some individuals. Response tendencies do not, however, necessarily translate into visible emotional responses. An

individual's emotion regulation determines whether the generated emotion experience translates into a visible emotional response. *Emotion regulation* is how individuals influence the emotions they have and how they experience and express their emotions.

Research by James Gross suggests that emotion regulation can occur at two points: (a) antecedent to the activation of emotional response tendencies and (b) after the emotion has been generated. Antecedent-focused emotion regulation techniques act on the stimuli coming into the system before emotional response tendencies are activated. Techniques include selecting or modifying situations to alter the emotional stimuli (e.g., avoiding an angry customer); thinking about something different to avoid the stimuli; or cognitive change, which involves attaching a different meaning to the situation. Response-focused emotion regulation works only on changing the outward expression of emotion, not the emotion itself. Suppressing the emotion is a common response-focused strategy. Although antecedent- and response-focused emotion regulation may look similar in terms of outward expression of emotion, their effects are actually quite different. Specifically, when presented with a negative emotional stimulus, suppression changes the outward expression of emotion but not the subjective experience. Suppression also produces increased sympathetic nervous system activation and decrements in cognitive functioning, whereas antecedent-focused coping strategies do not.

Distinctions between types of emotion regulation strategies highlight the importance of differentiating between the experience and expression of emotion. We typically make judgments of people's emotional state based on their expressive behavior: facial expressions, vocalizations, and body posture. What we can see, however, is only emotional expression. Individuals differ in terms of *emotional expressivity*, the extent to which they express outwardly the emotions they are experiencing. Differences in expressivity are a key to understanding the common stereotype that women are more emotional than men. The stereotype is not true: research demonstrates that males and females do not differ reliably in terms of emotional experience. What is true is that women are more emotionally expressive than men. Although men and women experience similar types of emotions, women are more likely to manifest those emotions behaviorally than are men.

EMPLOYEE ASSISTANCE PROGRAM

Employee assistance programs (EAPs) have various forms and offer different services across organizations but are generally thought of as systems of programs and resources implemented to support the health and well-being of an organization's employees. An organization may choose to institute an employee assistance program (EAP) for many reasons, including cost reductions, health care or employee turnover, and prevention and treatment of problems or disorders that may directly affect the organization's productivity or quality of services.

Employee assistance programs offer help with various problems encountered by employees, both personal and work related. Although there are no requisite services that must be offered to deem the organizational assistance as an official EAP, typical services include, but are not limited to, the following: counseling for substance abuse, including alcoholism; family or marital issues; problems with coworkers or supervisors; productivity issues, which may be related to personal issues, such as financial or health concerns; problems with sexual harassment or discrimination;

safety issues or infractions; and individual assistance with emotional or behavioral problems offered to both the employee and the employee's immediate family members. An organization's employees either are referred to EAP services via management or are self-referred, meaning the employee contacts the EAP without an internal referral.

HISTORICAL DEVELOPMENT OF EMPLOYEE ASSISTANCE PROGRAMS (EAPs)

Current models of EAPs emerged from the late 19th and early 20th centuries, when concern arose about consumption of alcohol in the workplace. At that time, it was commonplace for employees to drink on the job, and employers viewed this behavior as normative and thus acceptable. The foundation of today's EAPs can be traced back to several historical motivations, which raised public concern about alcoholism and alcohol use on the job. The Washingtonians, forerunners of Alcoholics Anonymous (AA), played a vital role in the movement through their attempts to persuade the public about the negative effects of workplace drinking on employee safety and health. During this time, the movement gained strength, with support from both the medical community and published studies documenting the effects of alcohol on workplace efficiency. The emergence of Taylorism (named for Frederick Taylor), a philosophy that emphasized implementation of the most efficient production systems, as well as workers' compensation laws focused on worker safety, further ignited concern and sparked initiatives to eradicate alcohol from the workplace.

Another catalyst for the emergence of EAPs was the mass production requirements incumbent on workers during World War II. Not only were workers who were under the influence of alcohol less efficient on the job, but they were also less dependable, resulting in higher absenteeism and reduced efficiency for the organization. Therefore, the earliest EAPs, also known as *occupational alcoholism programs* (OAPs), emerged in the mid-1940s with the primary goal of eliminating alcohol from the workplace by assisting and treating employees with alcohol problems. The ideal resolve was to return these workers to the workplace, alcohol free, and operating as productive members of the organization.

Early forms of EAPs remained secretive about their intentions and actions, but in the 1950s, formal and

written policies became standard. Still, programs rarely dealt with employee issues outside of alcoholism. Throughout the 1960s and 1970s, EAPs expanded to include employee assistance for issues including drug abuse, family problems, emotional or behavioral problems, legal problems, and financial problems. Beginning in the 1980s, EAPs further expanded to include more preventative, rather than reactive, assistance, including stress management and holistic health practices, such as assistance with smoking and overeating. This latter model has been referred to as an *employee enhancement program* (EEP) because of its focus on prevention. Other contemporary issues addressed by EAPs may include counseling or services for critical/acute stress incidents, such as the tragedies that occurred on September 11, 2001; workforce diversity and awareness, training that may also fall under employee development initiatives; and current mainstream information that may be beneficial for employees both on and off the job, such as how to prevent personal identity theft.

PROGRAM MODELS OF EAPs

Employee assistance program services may be offered using several different program models. A management-based, or in-house, program model, in which an organization maintains an in-house staff to coordinate EAP services, is the most typical arrangement found within organizations that are geographically centralized and have large employee populations. In this model, the EAP is usually considered a division of human resources and both the administrative and counseling/professional staff are employees of the organization. Another variation of an EAP is the contract model, in which an organization contracts services with one or more outside providers. Some companies choose to implement a blended-model EAP, which is a combination of a management-based model and a contract model. When a blended model is used, typically the administration is handled in-house and counseling/professional services are outsourced. Where unions exist, EAPs are sometimes called MAPs (member assistance programs), a name that emphasizes the involvement of union members in the determination of services. Regardless of the model, clinical staff have education and training in a variety of areas, including substance abuse and chemical dependence, crisis intervention, psychosocial counseling, and family issues. The

Employee Assistance Professionals Association (EAPA) now offers certification for employee assistance professionals. The Certified Employee Assistance Professional (CEAP) distinction requires a minimum of three years, or 3,000 hours, of experience in an EAP setting and successful completion of a written exam.

COMPONENTS OF AN EFFECTIVE EAP

Several factors must be considered in the development and implementation of an EAP to ensure its success. Most important, an organization's EAP must be endorsed by all levels of management, reflected in the provision of adequate financial and human resources, as well as public enthusiasm and support of the EAP's benefits to employees. Where labor unions exist, it is of vital importance that EAP professionals work with the union to create programs and services that accommodate the union members. Also of the highest importance is the clear message and consistent practice of confidentiality. Employees should be informed that any referral or assistance received from the EAP will not be included in the employee's personnel file, nor will any information they share be revealed to coworkers or supervisors. Confidentiality is extremely important in a workplace counseling setting, because without its guarantee, employees may be deterred from seeking assistance for fear of reprisal. An organization's EAP should also adopt a philosophy and mission statement, as well as establish program goals and objectives against which program evaluations should be conducted on an ongoing basis.

EMPLOYEE GRIEVANCE SYSTEMS

Grievance systems are formal organizational procedures designed to address employee complaints. These employee complaints, hereafter referred to as *grievances*, can range from general disputes about organizational policies (e.g., disputes about interpreting the vacation policy), to specific disputes about how the employee was treated (e.g., conflict with coworkers), to disputes that have legal implications (e.g., racial discrimination).

Grievance systems vary by organization. However, grievance systems typically have several (four to five) hierarchical steps that are used to address conflicts in the organization. Often the lowest level or step of a grievance system in a nonunionized organization is a written complaint or informal discussion with the employee's immediate supervisor. The first step in a unionized organization usually requires employees to talk or file a complaint with the union steward (representative). Higher steps of a grievance system usually consist of the employee presenting his or her complaint to higher levels of management. In a unionized context, the employee would receive union assistance or representation in presenting the complaint to the higher levels. The final step of grievance systems may consist of presenting the complaint to the highest level of administration (e.g., the CEO), a peer review panel (similar to a jury of peers), or an arbitrator (a neutral person who makes a final decision, similar to a judge).

Another common characteristic of grievance systems is that they are appeal procedures. This means that employees make the initial grievance at the lowest level and an initial decision is made. If the employee is not satisfied with the decision, he or she can appeal the decision to increasingly higher levels until satisfied with the decision or until all the steps have been exhausted. Because of these characteristics, grievance systems are also referred to as *multilevel appeal systems*.

WHY DO ORGANIZATIONS HAVE GRIEVANCE SYSTEMS?

The earliest grievance systems were created because of unionization. Specifically, they were created to

handle conflicts related to interpreting or implementing the collective bargaining agreement (a type of contract) that had been negotiated between the union and management. Unions promoted grievance systems as a voice mechanism or as a way to address employee concerns without risking retaliation from management and were considered a key feature for motivating employees to form a union.

Today, organizations voluntarily implement grievance systems in nonunion and union organizations for a variety of reasons. First, some research indicates that grievance systems may serve to reduce costs. For example, they may help identify and resolve organizational problems that could, if not properly addressed, lead to costly outcomes such as employee turnover. They are also considered an inexpensive alternative to litigation and may mitigate an employer's legal liability. Second, organizations may implement grievance systems to enhance the likelihood of increasing the positive outcomes (such as higher employee commitment to the organization) associated with employees feeling fairly treated and conflict being handled effectively. Finally, there is considerable evidence that organizations voluntarily implement grievance systems to reduce the likelihood of successful unionization of their employees.

THEORETICAL ROOTS OF GRIEVANCE SYSTEM RESEARCH

Two main theoretical models have been used to examine grievance systems. The first approach, the exit-voice model, was introduced by a labor economist, Albert Hirschman, to explain consumer behavior but was later applied to the employment context. According to the model, an organization learns about workplace problems via two major methods: exit or voice. The *exit* method is when employees leave the organization, and the *voice* method is when employees complain about the problem directly to the organization (e.g., grievance filing). The voice method is considered better for the organization, because organizations can learn about the problem directly and more quickly. This model predicts that more loyal employees will use voice methods to communicate workplace complaints and voice (e.g., grievance system activity) will be associated with positive outcomes for the organization.

The second theoretical approach draws from the due process and procedural justice literature. In the grievance system context, this theoretical approach

focuses on elements of the grievance system as they relate to the perceived fairness of the system. According to this theoretical approach, the perceived fairness of the system will be associated with higher grievance system usage.

PREDICTORS OF GRIEVANCE FILING

There are a number of ways in which an employee can address a complaint about a workplace issue besides filing a grievance. An employee could try to resolve the complaint on his or her own by discussing it informally with the other party, or the employee could use some alternate dispute resolution services provided by the employer, such as using the assistance of an ombudsperson or mediator. An individual could also pursue litigation through the courts system or choose not to address the complaint at all. This range of possibilities for addressing complaints has led several scientists to examine factors that relate to the use of grievance systems.

There are considerable differences across industries and organizations in the extent to which grievance systems are actually used. The earliest research examined the relation between demographic characteristics (e.g., sex, race, age) and grievance filing (using the grievance system). The findings were generally weak and inconsistent. That is, there is no strong support for the idea that one demographic group (e.g., younger workers) is more likely to file grievances than another group (e.g., older workers).

Today, scientists focus on how characteristics of the grievance system relate to grievance system usage. Most of this research draws from relevant due process and procedural justice theory. The empirical findings are largely supportive of this theoretical approach. For example, employees are more likely to use grievance systems that are considered more credible and have decision makers who are perceived to be fair and neutral. Another important factor is whether employees perceive there to be a low likelihood of punishment (being retaliated against) for grievance filing. Grievance systems that allow grievance filers to have an advocate assist them with the process are associated with higher grievance rates. This helps to explain why union grievance systems are used more frequently than nonunion grievance systems.

Some research focuses on how the characteristics of the organization and economy relate to grievance activity. Theoretical arguments suggest that the culture and norms within the organization for expressing disparate

views is related to grievance filing. Also, empirical evidence demonstrates that organizations that offer a number of different dispute resolution alternatives have lower grievance-filing rates. High unemployment rates are associated with higher grievance activity, suggesting that higher barriers to leaving the organization are important factors.

GRIEVANCE SYSTEM OUTCOMES

Most grievance system research focuses on examining the outcomes of grievance systems. Grievance system outcomes can be measured at both the organizational and individual levels. However, not all scientists agree on how to measure or interpret the measures of grievance system outcomes. The multiple approaches will be described in the following paragraphs.

Organizational Outcomes

One stream of research has applied the exit–voice model to examine the relation between having an organizational grievance system and outcomes such as lower employee turnover. Substantial research indicates that organizations that have grievance systems in place do have significantly lower turnover rates. We do not have any direct research evidence that implementing a grievance system is associated with higher employee productivity. Overall, this research is generally supportive of the predictions drawn from the exit–voice model—that is, the use of the exit option (turnover) can be reduced by providing a voice option.

Another stream of research has specifically examined grievance activity (the extent to which a grievance system is used) and organizational outcomes. Scientists in this stream of research argue that it is more important to consider whether the voice option is actually used than whether it exists. The empirical research suggests that higher grievance system usage is associated with more negative outcomes, such as lower productivity. It is difficult to determine whether the lower productivity results from grievance activity or if both grievance filing and lower productivity result from another, underlying problem, such as employees feeling low commitment to the organization.

Individual Outcomes

Also relevant is the effect of grievance systems on the individual employee. A number of studies compare the personnel records of grievance filers to

those of nonfilers. The general conclusion from this research is that individuals who file grievances experience negative outcomes. Specifically, grievance filers have significantly lower performance ratings, lower promotion rates, higher absences, and higher turnover rates than do nonfilers. In addition, grievance filers who appeal initial decisions and progress through higher levels of the grievance system appear to experience more negative outcomes. Based on these findings, scientists have concluded that, contrary to predictions from the exit–voice model, employees who exercise voice via a grievance system are punished for doing so. Specifically, scientists suggest that employee grievance filing is considered offensive or deviant behavior and managers punish that behavior consciously or unconsciously with lower performance ratings and limited opportunities for promotion.

However, other scientists argue that individual outcomes of grievance activity should be measured differently. In particular, these scientists argue that the negative outcomes attributed to grievance filing may actually result from experiencing a workplace dispute, rather than attempting to resolve it via a grievance system. In this approach, the individual outcomes of grievance filers are compared with individual outcomes of employees who had a complaint but chose not to file a grievance. Research in this area is limited, but there is some evidence that the individual outcomes of grievance filers are very similar to the individual outcomes of nonfilers who had a basis for a grievance but chose not to file one. Thus, it may be the reason for the complaint itself, rather than filing a grievance, that is the root of the negative outcomes.

SUMMARY

When an employee experiences a dispute, he or she may choose to make a complaint through an organization's grievance system, if one is available. Employees are more likely to use a grievance system to file a complaint if the grievance system is perceived as fair. Organizations that employ grievance systems appear to experience positive outcomes such as reduced turnover, yet the individuals who use the grievance systems may suffer negative consequences for doing so.

EMPLOYEE SELECTION

Employee selection is the process employers use to determine which candidates to choose for particular jobs or roles within the organization. (Some organizations select for a particular job, e.g., customer service representative, whereas others select for a role, e.g., management.) Often, *employee selection* connotes preemployment selection—that is, determining which external applicants to hire. However, the same term can also apply to a number of situations in which current employees are placed into an organizational role or job, including through promotions and transfers into new positions. Occasionally, the term *employee selection* is used broadly to refer to the process of selecting individuals to participate in initiatives such as management training programs, high-potential programs, or succession planning programs, in which the individual does not immediately assume a particular role or job but instead participates in some developmental process.

Candidates may be external applicants (i.e., applicants with no current association with the hiring organization) or internal candidates (i.e., current employees seeking other positions). However, employers sometimes seek candidates from only one source.

For example, in some organizations, candidates for a first-line supervisory job come only from the pool of current employees performing the position to be supervised. In other cases, the candidate pool may be limited to groups of applicants (i.e., nonemployees) because of the nature of the job. For example, employees in a large organization may not desire the lowest entry-level position. Either the individual already holds that position, or the individual perceives that position to be a step backward to be taken only in exceptional circumstances. Thus, the organization selects only from an external pool of candidates.

SELECTION INSTRUMENTS

Most organizations have a goal of identifying the best candidate or a capable candidate and use some sort of tool to help them evaluate a candidate and make decisions about whom to select. These tools may be what industrial psychologists consider a test, an objective and standardized sample of behavior. Generally, these would include traditional standardized paper-and-pencil tests or computer-administered tests, work samples, simulations, interviews, biographical data forms, personality instruments, assessment centers, and individual evaluations. However, many organizations collect information using tools that would not normally be considered tests, because the processes or instruments are either not objective or not standardized. Examples include résumé reviews, educational requirements, experience requirements, license or certification requirements, background investigations, physical requirements, assessments of past job performance, and interest inventories.

Selection procedures should measure job-related knowledge, skills, abilities, and other characteristics (KSAOs). The KSAOs measured depend on the job requirements and the tasks performed by the job incumbents. Typically, selection procedures used in business settings include measures of cognitive abilities (e.g., math, reading, problem solving, reasoning), noncognitive abilities (e.g., team orientation, service orientation), personality (e.g., conscientiousness, agreeableness), skills (e.g., electrical wiring, business writing), or knowledge (e.g., accounting rules, employment laws). Selection procedures that involve assessments of education and experience are generally used as proxies to assess knowledge and skill in a particular area. For example, a college degree in accounting and 5 years of experience as an accountant may

suggest that an individual has a particular level of knowledge and skill in the accounting field.

OBJECTIVES

When using employee selection procedures, employers have a number of objectives. Perhaps the most prevalent reason for employee selection is to ensure a capable workforce. Employers simply want to measure the job-related skills of the candidates to identify the most able or those who meet some minimum standard. In some cases, employers focus on other criteria, such as turnover, instead of or in addition to job performance. Higher levels of job performance lead in turn to organizational benefits such as higher productivity and fewer errors. When recruiting, hiring, and training costs are high, the advantages of lowering turnover are obvious.

Employers may use formal, standardized selection procedures to facilitate meeting other important organizational goals in addition to the enhancement of job performance. An organization may use these selection procedures to ensure a process that treats all candidates consistently. Other organizations may use these procedures because employee selection procedures incorporating objectively scored instruments are a cost-effective method of evaluating large numbers of people when compared with more labor-intensive selection methods such as interviews, job tryouts, work simulations, and assessment centers.

LEGAL ENVIRONMENT

Employee selection in the United States is heavily influenced by the legal environment. Federal laws, guidelines, and court cases have established requirements for employee selection and made certain practices unlawful. State and local legal environments are generally similar to the federal one, although in some states or localities, the requirements and prohibitions may be extended. Typically, the definitions of protected classes (i.e., subgroups of people protected by equal employment opportunity laws, such as racial and ethnic minorities and women) are broader at the state and local levels than at the federal level.

The federal requirements for employee selection are complex; however, the key elements include the following: (a) The selection procedure must be job-related and consistent with business necessity; (b) the selection procedure used does not discriminate

because of race, color, sex, religion, or national origin; (c) equally useful alternate selection procedures with lower adverse impact are not available; (d) the selection procedure should not exclude an individual with a disability unless the procedure is job-related and consistent with business necessity; and (e) adverse impact statistics must be kept. (*Adverse impact* is operationally defined as different selection ratios in two groups.) In addition, (f) where there is adverse impact, evidence of the validity of the selection procedure must be documented.

The laws for employee selection are enforced through two primary processes: (a) the judicial system and (b) enforcement agencies such as the Equal Employment Opportunity Commission, the Office of Federal Contract Compliance Programs, and a local human rights commission. It merits noting that the legal definition of an *employee selection procedure* encompasses all forms of such procedures, regardless of the extent to which they are objective or standardized.

CHOOSING THE TYPE OF SELECTION PROCEDURES

The kind of employee selection procedure used in a particular situation depends on many factors. Perhaps the most important consideration is the kind of knowledge, skill, ability, or other characteristic (KSAO) being measured. Some instruments are better for measuring some skills than others. For example, an interview is a good way to assess a person's oral communications skills, but it is not a particularly efficient means of determining a person's quantitative skills.

Industrial and organizational psychologists often consider the known characteristics of a particular type of employee selection procedure when choosing among various types of selection procedures. The typical levels of validity and adverse impact for an instrument may affect the choice of instrument. Most organizations want to maximize the validity and minimize the adverse impact.

Many organizational factors also influence the choice of selection procedure. Sometimes an organization will consider the consequences of failure on the job and design a selection process accordingly. When the repercussions of an error are high (e.g., death or bodily injury), the organization may use lengthy selection procedures that extensively measure many different KSAOs with a high level of accuracy. When the repercussions of an error are minor (e.g., wrong

size soft drink in a fast food order), the organization may opt for a less comprehensive process.

Some organizations consider other factors that are related to a high need for success in selection. Often, the cost of hiring and training and the time required to replace an individual who cannot perform the job at the level required influence the choice of selection instruments.

Some instruments may not be workable in the context of the organization's staffing process. A 2-day assessment center composed of work sample exercises and requiring two assessors for each candidate is not often practical when the hiring volumes are high. A test requiring the test taker to listen to an audiotope will not work if the equipment is unavailable. Some instruments may not be feasible with certain candidate groups. Candidates who are current employees may resist extensive personality assessments. Measures of past performance may not be feasible if the applicant pool contains external applicants. Some organizations attempt to minimize the need for reasonable accommodations under the Americans With Disabilities Act and avoid selection procedures, such as highly speeded tests, that often generate accommodation requests.

Most organizations consider the costs of selection instruments in their selection process. Often, selection procedures such as assessment centers, which typically cover many job-relevant KSAOs, present a great deal of face validity (i.e., the extent to which the measure looks like it would measure job-related KSAOs), and predict job performance well with moderate adverse impact, are rejected because of their costs. Some organizations systematically consider costs and benefits when choosing selection instruments and choose instruments that provide more benefits than costs. These organizations may be willing to spend a lot on selection procedures if the value of the resulting candidate pool is commensurately higher.

VALIDATING THE SELECTION PROCEDURE

Ideally, an employer uses a systematic process to demonstrate that a selection procedure meets the legal and professional requirements. Employers often avoid a systematic process when using less formal selection procedures, because they believe that such procedures are not required or fear the outcomes. However, compliance with current legal procedures generally requires some demonstration of job relevance and business necessity.

The validation process for a selection instrument typically involves determining job requirements, assessing the relationship of the selection process to those requirements, demonstrating that the selection process is nondiscriminatory, and documenting the results of the research.

Job analysis or *work analysis* is the process for determining what KSAOs are required to perform the job. The purpose of a job analysis is to define which KSAOs should be measured and define an appropriate criterion. A variety of techniques, ranging from interviews and observations to job analysis questionnaires, can be used to determine what tasks incumbents perform and what KSAOs are necessary to perform the tasks. The extent and formality of the job analysis varies with the particular situation. When tests that are known to be effective predictors of performance in a wide range of positions, such as measures of cognitive ability, are used, the job analysis may be less detailed than in cases in which a job knowledge test is being developed and information sufficient to support the correspondence between the job content and test content is necessary. Often when a test purports to predict criteria such as turnover, the need to analyze the job and demonstrate the relevance of turnover is obviated.

A *validation study* establishes a relationship between performance on the predictor and some relevant criterion. *Validity* refers to the strength of the inference that can be made about a person's standing on the criterion from performance on the predictor. Many ways exist to establish the validity of an inference, and current professional standards encourage an accumulation of validity evidence from multiple sources and studies. Perhaps the three most common approaches are content-oriented strategies, criterion-oriented strategies, and validity generalization strategies. *Content-oriented* strategies involve establishing the relationship between the selection procedure and the KSAOs required in the job, and *criterion-oriented* approaches involve establishing a statistical relationship between scores on the predictors and a measure on some criterion, often job performance. *Validity generalization* strategies (e.g., synthetic validity, job component validity, transportability) usually involve inferring validity from one situation in which formal studies have been done to another situation, based on demonstration of common KSAOs or tasks.

Demonstrating that selection procedures are nondiscriminatory is usually accomplished through a bias study. Accepted procedures involve a comparison of

the slopes and intercepts of the regression lines for the protected and nonprotected classes. Often psychologists will evaluate mean group differences and adverse impact; however, it is important to note that neither of these statistics indicates bias.

Government standards require documentation of research related to the job analysis, validity, and bias research. Careful industrial and organizational psychologists who want a successful implementation of an employee selection procedure will also provide detailed user's guides that explain how to use the selection procedure and interpret scores in addition to the technical report documenting the validity studies.

USING AND INTERPRETING THE RESULTS OF THE SELECTION PROCEDURE

Multiple ways to combine, use, and interpret employee selection procedures exist. Like the selection of a particular type of format for the employee selection procedure, the choice of how to use scores on employee selection procedures depends on scientific and practical considerations. Each approach has its advantages and disadvantages.

One of the first questions in using the results of selection procedure is how to combine data from multiple procedures. Two approaches are frequently used. In a *multiple hurdles* approach, the standard on one selection procedure must be met before the next is administered. In a slight variation, all selection procedures are given, but the standard on each procedure must be met for a candidate to be qualified. Another approach frequently used is the *compensatory model*, in which all components of a selection battery are administered and a standard for a total score on the battery must be achieved.

Multiple hurdles approaches have the advantage of ensuring that a candidate possesses the minimal level of the KSAOs being measured to perform the job at the level specified by the organization, whereas a compensatory model allows for a higher level of skill in one area to compensate for lower skill in another. For example, strong mental abilities may compensate for low levels of job knowledge: a candidate may not have all the job knowledge needed but may possess the ability to acquire additional knowledge quickly and efficiently. There are situations in which skills are not compensatory, and minimal levels of both are required. For example, in a customer service position, an employer may expect problem solving skills and

interpersonal skills. Some organizations prefer multiple hurdles because this approach allows them to spend their staffing resources wisely. For example, an organization may use a short test of basic reading skills to eliminate candidates who do not read well enough to complete a lengthy job knowledge test. In other situations, such as competitive labor markets, asking candidates to return for multiple testing events is not feasible. Consequently, organizations prefer a compensatory approach, or a modified multiple hurdles approach in which all instruments are given to all candidates.

Whether looking at one selection procedure or a combination of procedures, there are several ways to use the scores. In *top-down hiring*, the employer chooses the top scorer, then the next highest scorer, and so on, until the positions are filled. Top-down hiring maximizes performance on the criterion and frequently results in the highest levels of adverse impact, particularly when the employee selection procedure contains a significant cognitive component. Top-down selection procedures work well in *batch* selection—that is, the selection procedure is administered to a large number of individuals at one time, and all selections are made from that pool. When selection is *continuous*, meaning the selection procedure is administered frequently, the top of the list changes often, making it difficult to provide information to candidates about their relative status on a list of qualified individuals. In addition, if the skill level of the candidates tested is low, the employer runs the risk of selecting individuals who lack sufficient skill to perform the job at the level required by the organization.

Cutoff scores are often used to solve the problem of identifying who is able to perform the job at the level specified by the organization, specifying the pool of qualified people, and reducing the level of adverse impact. Using a cutoff score, the employer establishes for the procedure a minimum level that each candidate must achieve. Typically, all candidates who score above that on the procedure score are considered equally qualified. Although this approach solves several problems, it reduces the effectiveness of the selection procedure by treating people with different skill levels the same. The extent to which adverse impact is affected depends on where the cutoff score is set.

Both top-down selection and cutoff scores can result in individuals with very similar scores being treated differently. Sometimes banding is used to overcome this problem by grouping individuals with

statistically equivalent scores. Yet the bounds of the band have to be set at some point, so the problem is rarely surmounted completely.

Another approach that is often used by employers is the *piece of information* approach. The staffing organization provides the score on the employee selection procedure and interpretive information such as expectancy tables, and allows the hiring manager to determine how to use the selection procedure information and combine it with other information. For example, a hiring manager might compare test information with other indicators of achievement, such as college grade point average, and make a judgment about the mental abilities of a candidate. The advantage to this approach is its recognition that no test provides perfect information about an individual. The problem with the approach is that it opens the door to inconsistent treatment across candidates.

USEFULNESS OF AN EMPLOYEE SELECTION PROCEDURE

The usefulness of a selection procedure can be assessed in several ways. One approach determines the extent to which the number of successful performers will increase as a result of using the employee selection procedure by considering three factors: (a) the validity of the instrument; (b) the selection ratio (i.e., the percentage of candidates to be selected); and (c) the base rate for performance (i.e., the percentage of employees whose performance is considered acceptable). Another approach is to calculate the dollar value of using the selection procedure by applying utility formulas that take into account the research and operational costs of the tests, the dollar value of better performers, the number of employees hired per year, the average tenure, and the validity of the test.

EMPLOYMENT AT WILL

Since the late 1800s, absent a contract specifying otherwise, an employment agreement generally has been regarded in the United States as being terminable at will by either employee or employer. In practice, the doctrine primarily inured to the benefit of the employer, who was able, according to one court, to discharge or retain employees with any or no cause. This extreme characterization began to erode shortly before the 1950s, although employment at will remains a viable doctrine and the basic law in a majority of the United States.

Several factors limit the reach of the employment at will doctrine. For example, in the public sector, most employees have a constitutionally protected right to notice and a hearing, embodied in civil service regulations, before they may be terminated. Most collective bargaining agreements contain provisions that a covered employee may be terminated only for good cause and frequently require arbitration requiring the employer to prove the existence of good cause. Generally, employees may not be terminated for any discriminatory reason such as those proscribed by Title VII or other federal or state antidiscrimination statutes. Finally, almost all of the states have imposed some limits on the doctrine through legislative or judicial (common law) intervention. Three areas of statutory and common law exceptions to employment at will, especially developed since 1980, are summarized in the following sections.

VIOLATION OF PUBLIC POLICY

This exception, the most significant limitation, is based on tort law providing a cause of action that a discharge is wrongful if it violates some well-established public

policy. Although some form of public policy exception is recognized in nearly all states, exactly what constitutes a public policy varies widely. Most commonly, it must be proved that termination was because of retaliation, malice, or bad faith. Many states require that a public policy be expressly stated in a statute or be derivable from some constitutional provision. These cases frequently fall into one of four categories—for example, it is a violation of public policy if an employee is terminated for (a) refusing to violate a statute (commit perjury); (b) performing a statutory duty (jury duty); (c) exercising a statutory right (filing for workers' compensation); or (d) reporting a statutory or regulatory violation (by the employer). Courts in other states have been more willing to find an exception where policy is found to be fair and in the public interest. Thus, discharge of an employee who cooperated with law enforcement authorities investigating criminal activities of a coworker was held to violate public policy. In another case, a court held that it was a violation of public policy to discharge an armored truck driver who left the vehicle to save the life of a woman being threatened by an armed bank robber.

On the other hand, it must be stressed that a counterexample may be proffered for each of the foregoing cases. For example, at least one state has held that it was not a violation of public policy when an employee was terminated in retaliation for filing for workers' compensation.

COVENANT OF GOOD FAITH AND FAIR DEALING

An implied duty of good faith and fair dealing in the manner of performance and enforcement generally is taken to be part of every contract (not employment contracts only). For example, dismissal of an employee to deny payment of a sizable bonus that was due for concluding a substantial sale to a client was held to violate the covenant. Again, other courts have held otherwise, and less than a third of the states recognize the covenant as an exception to the at-will doctrine. Of those, many allow only the damages awardable under a claim of breach of contract.

BREACH OF IMPLIED CONTRACT

Courts have shown an increasing receptivity to finding implied promises of employment security that

are contractually binding. Typically, such promises are found in oral representations during applicant interviews or by supervisors, or in employee handbooks and personnel manuals. More than half of the states recognize this exception to employment at will. For example, an implied contractual commitment to job security was found in the policy manual of an employer that stated that it was the employer's policy to retain the services of all employees as long as their job performance was effective and efficient. In addition, the manual explicitly defined different types of termination; the definitions of disciplinary discharge and discharge because of performance were held clearly to imply discharge only for good cause. Employers may avoid such implied promises by well-drafted and conspicuous disclaimers, preferably acknowledged by the employee receiving the handbook or manual, a measure that is increasingly followed.

CONCLUSION

Because of the extreme variation among the states as to how the employment at will doctrine shall be interpreted, employers must be vigilant in keeping abreast of legislative and common-law developments in their jurisdictions. A Model Employment Termination Act (META) was proposed by the National Conference of Commissioners on Uniform State Laws in 1991 that would limit involuntary termination only to circumstances where there was good cause, but it has not been widely adopted or followed. Consequently, only the United States remains as a major industrial democracy that permits the termination of employees without valid reason.

EMPLOYMENT INTERVIEW

The employment interview is one of the most common methods organizations use to recruit, screen, and select employees. Few individuals are hired without going through at least one interview. Generally defined, an *employment interview* is an interpersonal exchange between a job candidate and one or more organizational representatives who attempt to assess the candidate's job-relevant experience and knowledge, skills, abilities, and other characteristics (KSAOs) to make a personnel decision. Although the typical interview involves a face-to-face interaction between candidate and interviewer, alternative interview modes such as telephone and videoconferencing are becoming increasingly prevalent.

Organizations use employment interviews for three main purposes: recruiting, screening, and selection. Recruiting interviews are used to provide information about a job and organization to individuals, with the primary goal of attracting potential applicants. Screening interviews take place early in the hiring process and are used to determine whether individuals are minimally qualified, as well as to assess the fit between an individual's goals, values, and interests and those of the hiring organization. Finally, selection interviews generally take place later in the hiring process (e.g., after some applicants have been screened out on other selection criteria) and are used to assess the extent to which candidates possess the experience and KSAOs important for success on the job. Selection interviews are also used to evaluate candidates for promotion within an organization.

Scholars have studied numerous aspects of the employment interview. Because most research has focused on the use of interviews for selection (rather than for recruitment and screening), the current discussion will focus primarily on findings relevant to selection interviews. However, many of the research findings are also applicable to recruiting and screening interviews.

SOCIAL AND COGNITIVE FACTORS IN INTERVIEWS

The social nature of the interview distinguishes it from many other types of selection techniques, such as paper-and-pencil and computer-based tests. Therefore, a great deal of research has examined how the

interaction between candidate and interviewer influences interview outcomes. Unlike some other kinds of selection techniques, for which a candidate's score is primarily under his or her control, high performance on an interview requires both the candidate to perform well and the interviewer to recognize that performance and assign high ratings. Therefore, researchers have also studied the role that interviewers play in the interview process, particularly how their decision-making and cognitive processes can affect interview outcomes.

There is evidence that a variety of social and cognitive factors can influence interviewer ratings. Unfortunately, these factors tend to be irrelevant to the KSAOs interviews are designed to measure, thus making their influence problematic. Below are some of the most common research findings in this area.

- Interviewers tend to overweight negative information and information obtained near the start of the interview (i.e., *primacy effects*) and near the end of the interview (i.e., *recency effects*).
- Some interviewers assign higher ratings to candidates who are similar to them on characteristics such as race, sex, education, and social background (i.e., the *similar to me* effect).
- Interviewers can be influenced by various nonverbal cues from interviewees, such as physical attractiveness, smiling, and eye contact.
- Interviewers tend to allow their preinterview impressions of candidates (e.g., based on their employment application) to influence their interview evaluations. For example, interviewers often unknowingly allow their initial impressions to affect how they gather and interpret information during an interview.
- Interviewers are often influenced by a variety of impression management behaviors, which many interviewees use to present themselves in a favorable light. For example, impression management tactics such as overemphasizing one's role in past successes and complimenting the interviewer have been shown to result in higher interview scores.

Although these factors can have a detrimental impact on interview outcomes, their effects tend to be rather small. In addition, some of these factors may be related to success on the job (e.g., smiling and eye contact for customer service jobs, impression management behaviors for sales positions), and therefore their influence may actually increase the validity of interviewer judgments in some cases.

THE IMPORTANCE OF STRUCTURE

Given the potential influence of the social and cognitive factors discussed above, researchers have attempted to identify ways to help interviewers focus on job-related information. The most significant finding in interview research over the past two decades has been that adding structure to the development, conduct, and scoring of employment interviews can result in a variety of positive effects. Michael Campion and his colleagues identified 15 ways to increase the structure of interviews. These elements are summarized here, beginning with seven characteristics that pertain to the content of structured interviews.

1. Design interview questions to assess the critical KSAOs identified by a job analysis.
2. Ask all candidates the same or highly similar questions to ensure that every job candidate receives the same opportunity to perform in the interview.
3. Limit prompting and follow-up questions to keep the interview as consistent as possible across candidates and discourage interviewers from leading candidates toward desired responses.
4. Use effective types of interview questions. Past behavior and situational questions are perhaps the two most researched types of structured questions. Past behavior interview questions ask candidates to describe how they behaved in previous situations relevant to the targeted KSAOs, whereas situational questions ask candidates how they would behave in hypothetical situations relevant to the job.
5. Include a large number of questions (e.g., 10 to 15) to maximize the amount of job-relevant information obtained during the interview.
6. Limit interviewers' exposure to candidate information (e.g., application forms, résumés, test scores) so that such information does not bias their judgments of candidate performance during the interview.
7. Limit the amount and type of questions candidates may ask during the interview, as uncontrolled questions can reduce the standardization of the interview.

The last eight characteristics of structured interviews pertain to how interviewers evaluate candidates' performance during the interview.

8. Have interviewers make multiple ratings, either by rating candidates' responses to each question or by rating each KSAO or behavior the interview is

designed to measure. Rating such subcomponents of the interview is thought to be less cognitively demanding for interviewers and may increase the reliability of the overall interview score.

9. Have interviewers make their ratings using a common set of detailed rating scales so that all candidates are evaluated on the same criteria.
10. Have interviewers take detailed notes regarding candidates' responses to each structured interview question to help them recall what candidates said during the interview.
11. Use multiple interviewers (in either a single panel interview or in multiple individual interviews) to help increase the reliability of interview scores.
12. When possible, use the same interviewers to evaluate all job candidates to ensure that one candidate is not selected over another simply because he or she happened to draw a lenient interviewer.
13. Ask interviewers not to discuss candidates between interviews, as such discussions could cause interviewers to change their standards for evaluating subsequent candidates applying for the same job.
14. Train interviewers to conduct and score interviews to help ensure the consistency of the interview process.
15. Combine interview ratings using statistical techniques (e.g., by computing the average rating) rather than by having interviewers integrate interview information themselves to derive an overall rating.

Clearly, increasing the structure of employment interviews can involve many factors. Thus, interviews tend to vary on a continuum of structure rather than being classified simply as structured versus unstructured. Although it is not always possible to incorporate all of the elements of structure described here, research generally indicates that increasing the level of interview structure tends to result in more valid and reliable judgments than those formed on the basis of less structured interviews. Research has also shown that interview structure is positively related to favorable decisions for defendants (i.e., hiring organizations) in employee discrimination cases. Nevertheless, very little is known about the relative contribution of specific elements of structure to the various outcomes discussed in the following section.

OUTCOMES OF EMPLOYMENT INTERVIEWS

Considerable interview research has focused on outcomes important to organizations, including reliability,

validity, equal opportunity, and applicant reactions to employment interviews. Some of the key results of this research are summarized in the following paragraphs.

Reliability

One important factor in judging the quality of interview outcomes is the extent to which interviews yield reliable scores. In an interview context, *reliability* is often defined as the extent to which different interviewers' ratings of the same set of job candidates result in a similar rank order of candidates for the position. Research results suggest that employment interview ratings can have acceptable interrater reliability. One of the main findings is that the average reliability coefficient for more structured interviews (.67) is higher than the average coefficient for less structured interviews (.34).

Criterion-Related Validity

Another important outcome is whether interviewer ratings can predict how well candidates would perform on the job if they were selected. The *criterion-related validity* of interviews is assessed by correlating interview scores with criteria of interest to organizations, such as training success, job performance, absenteeism, and turnover. Most studies have examined the relationship between interview ratings and job performance. After accounting for factors such as unreliability in the performance measure, correlations between interview ratings and performance typically range from .14 to .33 for less structured interviews and from .35 to .57 for more structured interviews. These results suggest that structured interviews are one of the most effective selection techniques for predicting job performance.

Incremental Validity

Organizations often use a combination of selection instruments to evaluate job candidates. Because interviews (particularly structured ones) tend to require a lot of time and resources to develop and administer, it is important to determine whether an interview will predict valued criteria (e.g., job performance) over and above the prediction provided by other, less expensive selection instruments. Several studies have found that structured interviews can have *incremental validity* when used with other selection measures,

such as cognitive ability tests, personality inventories, and situational judgment tests. Results suggest that adding a structured interview to a selection process can increase the criterion-related validity of the overall process by as much as 20%.

Equal Opportunity

Equal opportunity is another significant criterion on which selection techniques are evaluated. Most organizations want selection procedures that predict valued outcomes (e.g., job performance) but that also allow job candidates from different backgrounds an equal opportunity to succeed. Although ensuring equal opportunity is often a goal of organizations, the use of fair selection procedures is also important for ensuring that decisions based on selection scores are legally defensible. Research suggests that interview score differences between candidates from different racial and ethnic groups (i.e., Whites versus African Americans and Hispanics) tend to be small to moderate in magnitude. In addition, there is evidence that increasing interview structure can reduce ethnic group differences. Fewer studies, however, have examined the extent to which interviews yield similar scores for individuals who vary on other demographic characteristics, such as gender and age.

Applicant and Interviewer Reactions

Organizations have become increasingly concerned with how job candidates perceive selection procedures. For example, applicants' reactions are believed to affect how they perform on selection instruments, whether they decide to withdraw from the selection process, the probability they will accept a job offer, and even how likely they are to file lawsuits owing to the perceived unfairness of organizational hiring practices. Job candidates' reactions to employment interviews are typically among the most favorable of any type of selection method. For example, people believe that how candidates perform on an interview is generally a good indicator of how they will perform on the job if selected (e.g., interviews have high *face validity*). However, much of this research has examined applicant reactions to less structured interviews. Less is known about how candidates react to highly structured interviews. It is likely, for example, that job candidates might react negatively to some of the characteristics of structured interviews described earlier, such as limiting questions

from candidates, the use of multiple interviewers, and interviewer note taking.

As discussed, interviews involve an exchange of information between a job candidate and one or more representatives of an organization. Thus, it is also important to consider how *interviewers* react to different aspects of the interview process. Scholars have recently begun to investigate how interviewers perceive more structured interview formats. Despite the various benefits associated with structured interviews, initial results suggest that many interviewers still prefer interviews with less structure. For example, some interviewers feel that highly structured interviews do not allow them to control the conduct and scoring of the interview.

THE INTERVIEW AS A METHOD

Finally, it is important to note that the interview is a *method* of collecting information about candidates rather than a psychological construct such as cognitive ability or personality. In other words, the specific content of interviews (e.g., the interview questions) depends on the KSAOs and behaviors organizations want to assess in job candidates. Although interviews offer organizations the flexibility to evaluate a wide range of KSAOs/behaviors, there is relatively little research on how well interviews actually measure specific job-relevant attributes (e.g., interpersonal skills). Furthermore, studies that have attempted to examine this issue have not found strong evidence that interviewer ratings reflect the intended constructs. Thus, although employment interviews have been shown to have useful levels of criterion-related validity for predicting various outcomes, to date, less is known about the *construct-related validity* of interviewer ratings.

In addition to the flexibility of using interviews to assess a variety of job-related attributes, interviews can be conducted in several different modalities, including face-to-face, telephone, and videoconferencing interviews. Some organizations also video- or audiorecord face-to-face interviews and then distribute the recordings to raters to observe and evaluate. Such interview methods offer several advantages to organizations. Perhaps the most salient benefit is that they allow interviewers in geographically dispersed locations to evaluate job candidates without having to travel, thereby reducing the cost associated with face-to-face interviews.

Recent research has investigated whether alternative interview methods are comparable to the

traditional face-to-face method. Most studies have examined applicant reactions to different interview methods. The general finding is that applicants, and to some extent interviewers, seem to prefer face-to-face interviews to telephone and videoconferencing interviews. Other research has found that alternative methods tend to result in lower interview scores than those based on face-to-face interviews. Very few studies have investigated whether alternative interview methods differ on factors such as validity, reliability, or equal opportunity, although there is some evidence that structured telephone interviews have similar levels of criterion-related validity as do face-to-face interviews.

SUMMARY

Employment interviews play a key role in the hiring process for virtually all jobs. Early reviews of the interview literature were pessimistic about the usefulness of the interview as a selection technique. This pessimism was likely caused by the extensive use of less structured interview formats and by research showing how various interviewee and interviewer factors can unduly affect interview outcomes. The advent of structured interviews, however, has reestablished the interview as an effective method for evaluating job candidates. There is evidence that structured interviews can predict important outcomes such as job performance, can provide incremental validity beyond that of other selection techniques, and tend not to produce large score differences among candidates from different ethnic backgrounds. Furthermore, because the interview is a method, it can be used to assess a variety of job-relevant attributes. Although much has been learned about the employment interview, more research is needed to determine (a) what elements of structure are most important for reliability and validity, (b) how interviewees and interviewers react to different aspects of structure, (c) what types of attributes employment interviews are best suited to assess, and (d) the extent to which alternative interview modes yield similar results.

EMPOWERMENT

Today, more than 70% of organizations have adopted some kind of empowerment initiative for at least part of their workforce. To be successful in today's business environment, companies need the knowledge, ideas, energy, and creativity of every employee, from frontline workers to the top-level managers in the executive suite. The best companies accomplish this by empowering their employees to take initiative without prodding, to serve the collective interests of the company without being micromanaged, and to act like owners of the business. So what is empowerment, and how can it be effectively implemented in work organizations?

Over the last two decades, two complementary perspectives on empowerment at work have emerged. The first focuses on the social structural conditions that enable empowerment in the workplace, and the second focuses on the psychological experience of empowerment at work. Each perspective plays an

important role in empowering employees and is described in the sections below.

SOCIAL-STRUCTURAL EMPOWERMENT

The roots of the social-structural perspective on empowerment are found in theories of social exchange and social power. The emphasis is on building more democratic organizations through the sharing of power between superiors and subordinates, with the goal of cascading power to lower levels of the organizational hierarchy. In this perspective, *power* means having formal authority or control over organizational resources and the ability to make decisions relevant to a person's job or role. In short, social structural empowerment is about employee participation through increased delegation of responsibility down throughout the organizational chain of command.

The goals of the social-structural perspective focus on understanding how organizational, institutional, social, economic, political, and cultural forces can root out the conditions that foster powerlessness in the workplace. Practically, organizations can change organizational policies, processes, practices, and structures from top-down control systems to high involvement practices in which power, knowledge, information, and rewards are shared with employees in the lower reaches of the organizational hierarchy. For example, management can change its policy to allow employees to decide on their own how they will recover from a service problem and surprise and delight customers by exceeding their expectations rather than waiting for approval from a supervisor.

Specific practices that exemplify a high involvement system include the following:

- *Shared decision making.* Employees and/or teams may have input into and influence over decisions ranging from high-level strategic decisions to routine day-to-day decisions about how to do their own jobs.
- *Performance-based pay.* Employees share in the gains of the organization and are compensated for increases in their own skills and knowledge.
- *Open flow of information.* This includes the downward flow of information (about strategic direction, competitive intelligence, and financial performance) and the upward flow of information (concerning employee attitudes and improvement ideas).
- *Leadership development and training.* Training enables leaders to do their own jobs better and also

may provide interpersonal/leadership skills and knowledge of the economics of the business.

However, although this perspective has garnered much attention by practitioners because it helps them see how the kinds of managerial actions can facilitate empowerment at work, it is limited because it provides an organization-centric perspective on empowerment. It does not address the nature of empowerment as *experienced* by employees. This is important because in some situations, power, knowledge, information, and rewards were shared with employees yet they still felt disempowered. And in other situations, individuals lacked all the objective features of an empowering work environment yet still felt and acted in empowered ways. This limitation helped to spur the emergence of the psychological perspective on empowerment, which is described in the next section.

PSYCHOLOGICAL EMPOWERMENT

Psychological empowerment has its roots in early work on employee alienation and quality of work life. Rather than focusing on managerial practices that share power with employees at all levels, the psychological perspective examines how employees experience empowerment at work. This perspective refers to *empowerment* as the personal beliefs that employees have about their role in relation to the organization. When people feel empowered at work, they experience four dimensions:

1. *Meaning.* Meaning involves a fit between the needs of one's work role and one's beliefs, values, and behaviors.
2. *Competence.* *Competence* refers to self-efficacy specific to one's work, or a belief in one's capability to perform work activities with skill.
3. *Self-determination.* Self-determination is a sense of choice in initiating and regulating one's actions. It reflects a sense of autonomy over the initiation and continuation of work behavior and processes (e.g., making decisions about work methods, pace, and effort).
4. *Impact.* Impact is the degree to which one can influence strategic, administrative, or operating outcomes at work.

Together, these four cognitions reflect an active, rather than passive, orientation to one's work role. In

other words, the experience of empowerment is manifest in all four dimensions—if any one dimension is missing, then the experience of empowerment will be limited. For example, if people have discretion to make decisions (i.e., self-determination) but they don't care about the kinds of decisions they can make (i.e., they lack a sense of meaning), they will not feel empowered. Alternatively, if people believe they can make an impact but don't feel like they have the skills and abilities to do their job well (i.e., they lack a sense of competence), they also will not feel empowered.

The social-structural perspective is limited because it is organization-centric, and the psychological perspective is also limited because it is individual-centric. A complete understanding of empowerment at work requires the integration of both perspectives. In the sections below, we describe the key research findings on the two empowerment perspectives.

RESEARCH ON EMPOWERMENT

Social-Structural Empowerment Findings

In terms of the social-structural approach on empowerment, much of the work has been conducted under the terms *high-involvement work practices* and *high-performance work systems* and has focused on organization-level outcomes. Programmatic research on high-involvement work practices has been conducted by researchers at the Center for Effective Organizations at the University of Southern California. Their research has shown that high-involvement practices that involve sharing power, information, knowledge, and rewards with employees at all levels have positive outcomes for organizations, particularly in terms of improvements to employee quality of work life, the quality of products and services, customer service, and productivity. Broader research in the area of high-performance work systems (these include employee involvement but also things such as long-term job security, flexible scheduling, and multi-skilling) shows similar findings but also documents the higher labor costs that are incurred with these practices.

Psychological Empowerment Findings

Unlike the social-structural perspective, in which many different instruments have been used to measure empowerment, a single measure of psychological empowerment has been predominately used in empirical

research. Much of the work on the psychological experience of empowerment has been conducted at the individual level of analysis, although more recent research has examined team-level empowerment. In terms of the demographics of empowerment, employees with higher levels of education, more tenure, and greater rank report experiencing more feelings of empowerment.

Research suggests that when people experience empowerment at work, positive outcomes are likely to occur. When employees experience more empowerment, they report less job strain and more job satisfaction and organizational commitment. They are also less likely to leave the company. But empowerment does not affect only employees' attitudes; it also affects their performance (i.e., managerial effectiveness and employee productivity/performance) and work behaviors (i.e., innovation, upward influence, and being inspirational to others).

Research on empowered teams also indicates positive outcomes. More empowered teams have better process improvement, higher quality products and services, and more customer satisfaction than less empowered teams. Empowered teams are also more proactive, less resistant to change, more satisfied with their jobs, and more committed to the team and the organization.

Recent research also suggests that empowerment is particularly important in certain kinds of contexts. Empowerment is found to be especially important in virtual settings where people do not have face-to-face interactions and must work independently. And empowerment has been found to be particularly important to preserve the hope and attachment of survivors during times of organizational downsizing.

Findings Linking the Social-Structural and Psychological Perspectives on Empowerment

Research has also examined the relationship between different elements of social-structural empowerment and the psychological experience of empowerment. In an array of studies, employees experience more psychological empowerment under the following conditions: wider spans of control between management and workers, more access to information about the mission and performance of the organization, rewards based on individual performance, role clarity, enriching job characteristics, and supportive

organizational cultures in which employees feel valued and affirmed. Strong work relationships also enable feelings of empowerment. Employees experience more empowerment when they have more sociopolitical support from subordinates, peers, superiors, and even customers. Employees also experience more empowerment when their leaders are approachable and trustworthy.

Although the above findings indicate that social-structural empowerment enables psychological empowerment, the converse is also true. Employees who experience empowerment at work seek out and shape their work contexts to further enable their empowerment. They act to create and sustain work environments that provide social-structural empowerment.

SOME KEY CHALLENGES IN BUILDING EMPOWERMENT AT WORK

Empowerment practices are implemented in hopes of building employee commitment, overcoming worker dissatisfaction, and reducing absenteeism, turnover, poor-quality work, and sabotage. But all too often these implementation efforts fail to achieve their hoped-for results. Why?

First, some managers confuse empowerment with a quick fix and give up before it has been successfully implemented. The transition from a more traditional command-and-control system to an empowered organization requires a culture change. It is not unusual for a culture change to take more than 5 years to be completed. Culture changes take discipline, consistency, and patience. The long-term approach necessary for successful empowerment implementation efforts appears at odds with a business environment that requires quarterly results. This long-term approach is especially difficult as leadership transitions bring frequent changes to the vision for the organization.

Second, sometimes there is confusion about what is meant by the term *empowerment*. For example, it is not uncommon for managers to tell employees that they are empowered but not explain what they mean by empowerment. An employee may make an assumption about what the manager means by empowerment—he or she responds enthusiastically by independently making a decision that might have required approval in the past. The manager responds negatively because he or she was just looking for employees to share more ideas with him or her, not actually make decisions on their own. The employee

feels dejected and returns to his or her old ways of working. As this scenario illustrates, a key issue is for managers to be clear and explicit about what they mean by empowerment.

Third, some managers lack the courage to genuinely empower their people. These managers are afraid they will lose control if they genuinely empower employees. They worry about loose cannons who are not aligned with the goals of the unit. They worry that employees will make mistakes. They assume that they alone are the source of the best ideas. These concerns are especially strong for managers who have spent significant time in command-and-control bureaucracies. Starting with small initial steps at sharing power, setting clear limits for empowerment, and building trusting relationships have been found to be effective mechanisms for reducing these concerns.

And fourth, some empowerment efforts fail because employees resist efforts at empowerment. A very small percentage of employees value the simplicity of following directions and being told what to do. Some employees have been trained and conditioned to follow orders for much of their work lives. Taking initiative will feel countercultural to them, and it takes time for them to learn to be more proactive. To empower them, managers can set up small initiative steps to build comfort and confidence. Training and development programs can also bolster their confidence to act in more empowered ways.

ENGINEERING PSYCHOLOGY

Ergonomics and human factors seek to enhance the fit between individuals and their work environments by applying knowledge of human abilities and limitations to the design of operational processes, system interfaces, training, and performance aids. Developed along similar lines as industrial and organizational psychology, the career field owes much of its early success to applications in support of military efforts in World War II. Of these early success stories, one of the most notable involved redesigning pilot controls on military aircraft in response to a large number of pilots flying their airplanes into the ground. Despite extensive training, the pilots were not able to control their aircraft under stressful emergencies, primarily because system design was in contrast to pilot expectations of how things should work. A lack of standardization between different aircraft models was improved by modifying the handles of the landing gear control into the shape of a wheel and the handles of the aileron control to resemble a wing, and these changes eliminated “belly landings” almost overnight.

What may seem trivial 60 years after the fact is actually an exemplar for the profession. Real-world operational problems (i.e., belly landings) led to an investigation of work processes (i.e., analysis of pilot tasks during landing) that served to identify a set of constraints that affected performance (i.e., pilots had to rapidly discriminate between two identical controls) and led to design modifications (i.e., alternative handles). This principled approach to the assessment and design of complex sociotechnical systems (e.g., an aircraft cockpit) is the cornerstone of the field.

In the ensuing 60 years, the field has expanded, and *human factors* is often presented as a catchall label for a discipline that encompasses tasks familiar

to engineering psychology, industrial engineering, ergonomics, systems engineering, human–computer interface design, and software usability. Most recently, human factors, along with much of psychology, has been greatly influenced by the advancement of cognitive science. A variety of theories and approaches, including naturalistic decision making, shared mental models theory, and metacognition, have markedly influenced current approaches. The result is a greater focus on the information-processing and decision-making aspects of job performance. Furthermore, the many recent advances within cognitive engineering and cognitive psychology provide human factors professionals with additional tools for knowledge elicitation and measurement of knowledge structures.

This broader context, leveraging interdisciplinary methods to enhance the relationship or fit between humans and work environments, can be thought of as a method of human-centered engineering (HCE). The objectives of HCE, therefore, are to understand human skills and knowledge, study and analyze work environments, design better interactions between humans and technology, and engineer better teams and organizations. The underlying intention is to prepare and enable humans to excel at their work. The use of models within HCE, both descriptive and executable, provides a framework to analyze work processes and identify opportunities and means for performance enhancement. Within this context there remains a focus on design that harks back to landing gear controls and views the work environment as changeable and a source of constraints on human performance. There are several defining characteristics of the HCE approach.

SYSTEMS APPROACH

Within HCE, the human operator is the central figure within a complex sociotechnical system composed of the operator, the technology (i.e., tools, computers, etc.) necessary to complete the required tasks, and the work environment (i.e., organization, physical setting, task requirements). These systems are characterized by common purpose, shared information networks, interactions between components, and imposed constraints that influence behaviors. Because of system complexity a structured, systematic approach to design and evaluation is required, simultaneously considering all components across the sociotechnical system.

A variety of models have been proposed to describe the system approach and the systems development process. Common to all are a set of stages that begin with a representation of the system requirements (i.e., operational needs) that facilitate a design process and evaluation methods. Additionally, they identify a wide range of HCE methods (i.e., task analysis, cognitive work analysis, decision support systems, etc.) that can be used to enhance the fit between the components of a sociotechnical system. Looking across these models, one is aware of a continuum of influence on the work environment. Within this context, HCE methods to enhance fit can be applied at the person (e.g., training), technology (e.g., interface design), or organizational (e.g., team design) level.

MODEL-BASED APPROACHES

The complexity of the systems approach provides a comprehensive method to understand, assess, and design for performance. This also creates a requirement to represent a variety of detailed parameters to describe a system. Therefore, the use of models within HCE has emerged as a key enabler to apply the system approach to ever larger and more complex systems. Models provide a useful mechanism to structure the design space and highlight the constraints that will affect overall system performance. Many modeling approaches exist, and a review is beyond the scope of the current entry.

One important benefit of a model-based approach is that it provides both reactive and proactive approaches. In the reactive mode, models can be developed to describe current systems, diagnose performance, and highlight areas for improvement. In a proactive mode, models can be used to predict and develop reasonable designs, providing both cost and risk reduction. Models are limited by the fact that they are representations of real-world systems and require some means of validation. Therefore, the results of modeling efforts ultimately require evaluation with prototype or test systems. The outcomes of these evaluations serve a dual use, as they can be used to iterate and refine both the models and the design.

KNOWLEDGE ELICITATION

The traditional systems approach and model-based approaches require an understanding of overall system processes. This understanding develops from a

variety of knowledge elicitation methods employed by HCE, including the following:

- *Cognitive task analysis.* This approach is a group of techniques that identify the cognitive processing requirements that are required when working with complex computer-based systems. To identify these requirements, the analyst interviews workers in the context of the work environment (contextual inquiry) about critical incidents or about critical decisions.
- *Cognitive work analysis.* This constraint-based method is performed in five stages. Each stage further constrains the next. The first identifies the physical work environment or system functions that must be considered. The second stage determines the tasks that must be accomplished. The third stage delineates the strategies that can be used in accomplishing those tasks. The fourth stage focuses on the socio-organizational aspects of completing the tasks using that strategy. The final phase defines the required worker competencies.
- *Needs analysis.* This method identifies the goals of the system, the environmental factors that will affect the needs of the system and the workers to reach these goals in this environment. There are several methods for obtaining this information, including interviews, observation, literature review, and critical incident analysis. Some of the information that will be gathered in this analysis includes, for example, the protective equipment to be used and whether it interferes with operation or maintenance, tasks to be performed to meet the goals, and information requirements to complete the tasks.

There are many variations on these and other techniques based on the position within the continuum of influence and the nature of the work. A central component of each, however, is a focus on the human cognitive and information processing requirements.

PROCESS DESIGN

Central to the systems approach are the interactions among the components of the sociotechnical system. As such, core to an HCE approach is assessment and design of the processes for using a system. Processes may be developed in parallel with new technologies or can be designed around existing technology. In either case, the objective is to improve the fit between worker and environment. A well-designed process is one in which individuals can easily learn and efficiently perform their tasks and understand the other

functions in the system. There are two components of process design: task analysis and work flow analysis.

Task analysis is the documentation of the tasks that are performed and the steps that these tasks comprise. The method to complete task analysis depends on the nature of the work. Analysis of cognitive tasks should be obtained through interviews often centered on atypical incidents; physical tasks should be observed. The information and equipment used, the time required, and the variety of methods employed should be included (especially noting differences between experienced workers and novices and methods of documentation).

In the *workflow analysis*, the analyst combs through the data documented in the task analysis looking for constraints, redundancies, and clusters of actions that require the same equipment or information. These are often demonstrated in differences between experts and novices. The analyst then develops a new process that eliminates redundancies and increases efficiency by having actions with the same equipment or information performed consecutively. These workflows must also consider infrequent but predictable situations (e.g., errors, increased volume, etc.). The more complex the system is, the harder it is to identify and evaluate all possible workflows for all possible situations. Therefore, models based on the constraints and the task analysis can be used to determine the best workflow for both typical and infrequent situations.

SYSTEM DESIGN

One of the most effective ways to enhance the fit between the human and the work environment is to design a system in which each of the following factors is considered:

- Technological constraints
- Environmental factors (temperature, ambient noise levels, etc.)
- Goals of the system
- User capabilities and limitations

Although these factors provide design goals, a more principled approach is needed to achieve desired outcomes. Some may view system design as a structured and formalized process, but it is less rigid in reality. A variety of design methods have evolved over time, providing the design practitioner with different approaches for different applications. Sample

approaches are listed below; however, it is important to identify the commonalities across them to understand the core elements of systems design.

A review of the system-design literature highlights key features necessary to ensure an effective design. The design process must create an integrated sociotechnical system that considers the organization (formal and informal), the interactions between the human organizations and the technological systems, and the constraints imposed by the environment. The process must also consider multiple operational situations or scenarios and allow for comparisons among these scenarios using prototypes or models. The design process must include the user throughout life-cycle development. Finally, the process must include iterations to facilitate redesign and modification, especially to make affordances for technological changes.

Examples of System-Design Approaches

- *Traditional system design*: This linear or waterfall approach spans from conceptual design to physical design to implementation and evaluation. This approach is generally believed to have become obsolete, as the capabilities of system technology have outpaced designers' abilities to understand all the design ramifications of these technological advancements.
- *Sociotechnical systems approach*: Design is driven by the analysis of the environment, the social system, and the technology system, with the objective of maximizing the fit among the three components.
- *User-centered design*: In this approach, the primary objective is to design systems that explicitly satisfy human operator task and information processing requirements. This approach emphasizes user involvement throughout the design process.
- *Participatory ergonomics*: This approach is related to user-centered design, with user involvement throughout the design process, but goes further, allowing users, with expert supports, to complete the design.

USER INTERACTION AND USABILITY

The user interface (UI) is the primary means by which a user interacts with a system. To the user, however, the UI is the system; very rarely does the user have a strong comprehension of how the system is actually working. Thus the UI must serve two functions: It must (a) provide users with an understanding of how the system functions and (b) permit users to operate the system in a manner that is most natural for them.

Therefore, the flow of information is a critical component to designing a user-friendly UI. There are several guiding cognitive-perceptual principles to consider:

- Logical display groupings (e.g., follow gestalt principles, etc.)
- Consistency of look and function (e.g., like items look and function similarly and vice versa)
- Labels are legible, visible, meaningful, and discriminable
- Controls are reachable and movable by the population in the work environment

These are not all of the concepts that must be considered, but it is clear that UI design in particular and system design in general can enhance or impede the effectiveness of the system.

SUMMARY

Human-centered engineering serves as a global term to describe a variety of methods, tools, and approaches associated with human factors, ergonomics, engineering psychology, industrial engineering, systems engineering, human-computer interface design, and software usability. As a discipline, HCE represents a powerful method to enhance the fit between humans and their work environment.

the phases of emergence, recognition, evaluation, and exploitation of opportunities). Small and medium-sized enterprises are the major agents of economic development and growth, adding new jobs, in contrast to most large companies. Entrepreneurial activity predicts wealth creation across nations. Entrepreneurs start new organizations and mold their organizational climate and culture. Entrepreneurial success (successful start-up, survival, firm growth) depends on the owners and may be a more useful (and a more objective) performance outcome variable than the supervisor ratings typically used in industrial/organizational psychology. Industrial/organizational psychology should, therefore, do more research on entrepreneurship.

A psychological model of entrepreneurship looks at distal variables of interpersonal variables, cognitive ability, school education, and experience and at proximal variables, such as cognitions (e.g., opportunity perception), motives (such as entrepreneurial visions and passions), and action strategies (e.g., proactive vs. reactive strategies). All of these factors should affect entrepreneurial success in interaction with situational and environmental conditions (such as industry, difficulty of doing business in an environment, and culture).

Meta-analyses and other reviews show that among the interpersonal variables, need for achievement, self-efficacy, cognitive ability, and expertise are clearly related to starting a business and business success. Similarly, entrepreneurial orientation, such as proactivity, innovativeness, competitive aggressiveness, risk taking, and autonomy, are related to starting a business and success. Only risk taking shows small correlations, and its importance is often overestimated.

The variables related to intelligence, education, and experience (often summarized as *human capital*) help small business owners to run their enterprises successfully. More recent resource-based theorizing argued for the importance of firm-specific knowledge and experiences for success that cannot be easily duplicated by competitors in the market.

The proximal variables relate to active exploration of business opportunities, which are strengthened by goals and action strategies, cognitive processes, and task-specific self-efficacy. High goals, visions, passion for work, and other motive patterns, as well as confidence in one's ability, predict success. Proactively and systematically approaching the environment and shaping it to a certain extent, rather than reacting to events, leads to success, as well. Cognitive

ENTREPRENEURSHIP

Entrepreneurship is about starting an organization, organizing effort, and exploiting opportunities (with

processes, such as helping to recognize present opportunities in the market and alerting entrepreneurs, as well as biases in cognition (such as a bias for optimism and illusion of control) seem to be important to distinguish entrepreneurs from nonentrepreneurs. One interesting issue is whether the proximal variables are mediators between distal variables and success. Recent evidence indicates that action planning and motivation mediate between personality and success.

Innovations and entrepreneurs are geographically clustered. Entrepreneurship has a social dimension—one function of entrepreneurs is to organize effort and, thus, to lead people. Entrepreneurs do better if they are well networked and if they possess social capital.

Entrepreneurs are nested in environments. There is some controversy about the function of the environment. Ecological approaches to entrepreneurship conceptualize the environment to determine start-ups and success. In contrast, psychological approaches emphasize the function of entrepreneurs' activities on the environment and the interaction between psychological and environmental variables (e.g., personality-by-environment interactions). There is, as yet, little theory and research on the relevant context conditions. Promising moderators in entrepreneurship research are environmental variables (hostility, complexity, predictability, controllability), industry tasks (e.g., service vs. manufacturing), national culture, and stage at the life cycle of the firm (such as prelaunch, launch, and postlaunch phases).

Ever since David McClelland's classic studies of entrepreneurs, psychologists have participated in training entrepreneurs to be more effective in the start-up of organizations and in managing new firms, and these efforts seem to be effective (although there is still a dearth of efforts to integrate newer industrial/organizational methods into this training and to evaluate the training, as pointed out by J. R. Baum, M. Frese, and R. A. Baron).

The field of entrepreneurship research is an interdisciplinary field to which industrial/organizational psychology can contribute substantially. Once industrial/organizational psychologists become more dominant in this field, this will also change industrial/organizational psychology itself by enabling the creation of more interesting questions and the development of an important area of applying psychological principles.

EQUAL PAY ACT OF 1963

The Equal Pay Act (EPA) was instituted in 1963 and was intended to prevent sex discrimination in wages. It is part of a larger architecture of fairness in wages known as the Fair Labor Standards Act (FLSA). This entry will not cover FLSA, but good reviews of FLSA by Cristina Banks and Lisa Cohen, as well as Arthur Gutman, are available to the interested reader. The EPA is one of the few employment statutes that identifies a single protected class (i.e., gender, although age is another protected category). The act permits unequal pay for men and women if any of the following foundations are used to determine pay: (a) bona fide seniority systems, (b) merit-based pay systems, (c) a pay system that uses quantity or quality of production as a basis for allocating wages, or (d) a system of allocation based on any factor other than sex of the employee. The act further prohibits an employer from *lowering* the wages of one employee group (i.e., men) to eliminate a wage differential between men and women. The act covers all employers, in both the private and public sectors, and an EPA claim can be applied to a workforce as small as two, as long as one is a man and the other a woman.

The EPA ushered in a new era of antidiscrimination laws applied to the workplace. Although initially the EPA was administered by the Department of Labor, the administration is now the responsibility of the Equal Employment Opportunity Commission (EEOC). During the period from 1992 to 2003, 1,200 claims on average were filed annually under the EPA statute, representing approximately 1% of all charges filed with the EEOC. Although this number may not seem substantial in a relative sense, the problem can be quite expensive from an absolute perspective. In part, this expense occurs because correcting the problem requires raising the lower salary rate and considering not only back pay, but also interest and denied salary

increases. As an example, Texaco paid \$3.1 million to underpaid female employees. Suits may be filed directly by an individual, by a class of claimants, or on behalf of an individual or a class by the EEOC. Violations considered to be willful or intentional often result in considerably greater monetary awards than those considered unintentional. Gutman has suggested that willfulness or intentionality might simply be construed as whether or not the employer was even *aware* of the existence of the EPA or the FLSA. This is a rather low threshold for the definition of *willfulness*. A more reasoned definition of willfulness might be that the employer knew or had reason to know that its compensation practices were in violation of the EPA.

The essence of the EPA is a determination of whether women are being paid less for substantially equal work done by men. This does not necessarily require that men and women have the same job titles. The definition of *equal work* is derived from four factors:

- *Equal skill required*: equal experience, training, education, and ability
- *Equal effort required*: equal physical and mental exertion
- *Equal responsibility*: equal accountability and supervisory duties
- *Equal working conditions*: equal physical surroundings and hazards

If there are substantial differences in *any* of these categories, the jobs are not considered equal for purposes of the EPA, although if there are minor differences, unequal pay could not be justified. An example of a typical EPA challenge was the case *Laffey v. Northwest Airlines*. The charge was that male “pursers” were paid more than female “stewardesses” (who would now be called *flight attendants*), even though both performed basically equal work.

THE CONCEPT OF COMPARABLE WORTH

As we have seen in this discussion, the foundation for the application of the EPA is the concept of *equal work*. This concept has been broadened in the human resources, industrial/organizational, and employment policy literature to one of *comparable work*. The EPA does not address the concept of *comparable work*, but limits itself to *equal work*. Nevertheless, the concept of comparable work for comparable pay may find some foundation in Title VII law. Although we will

not cover the legal arguments in this entry, we will briefly consider the concept of comparable worth.

In its simplest form, comparable worth means that people who are making equal contributions to the organization (i.e., input) are entitled to comparable pay (i.e., outcomes). One approach for reconciling input to outcomes is known as *job evaluation*. Typical job evaluation systems identify factors with differential weights that result in a recommended wage or salary level. Various levels of contribution are identified for each factor. The weighted and summed values for a given job are the basis for compensation determinations. There has been some criticism that these apparently objective systems for determining pay are themselves subject to various biases. Job evaluation systems produce estimates of *internal worth*. Thus, values emerge from a comparison of each job title with each other job title *within or internal to* an organization. Alternatively, an employer might conduct a wage or salary survey of other employers in the same business sector and/or geographic area. In this case, the comparison is among job titles *outside of or external to* the organization. Critics of external worth methods for determining compensation argue that current compensation architecture is simply a manifestation of the unfairness of the past decades.

The larger issue surrounding the debate about comparable worth relates to jobs that might be considered traditionally male or female. In this case, there is no easy way of comparing jobs with very different job titles or responsibilities. The determination of comparable contribution becomes more complicated. One must determine whether women are being underpaid or are just gravitating to jobs that are worth less to employers.

Robert Dipboye and Adrienne Colella suggested that organizations engage in one or all of three types of audit to determine the fairness of their pay policies:

1. *Equal pay analysis*: an examination of the relative pay for men and women in very similar jobs.
2. *Pay equity audit*: an examination of comparable worth using either internal worth (job evaluation) or external worth (employer compensation surveys), with a particular emphasis on jobs held predominantly by women within the organizations compared with those held predominantly by men.
3. *Across-the-board audit*: a more detailed analysis of the compensation rates for men and women within the organization, with an emphasis on identifying

any factors that might lead to observed differences. As an example, Dipboye and Colella suggested a statistical analysis of compensation levels for men and women within pay grades.

There is speculation that historical patterns of unfair compensation for women in the workplace may disappear as a function of the increasing membership of women in jobs traditionally held by men (e.g., public safety and trades) and the decreasing availability of women in certain jobs (e.g., nurse, secretary), thus resulting in higher compensation for those jobs. Nevertheless, Dipboye and Colella suggested that these social changes are likely to occur only in the context of a vigorous enforcement of both the EPA and Title VII.

EQUITY THEORY

Equity theory is a conceptualization that focuses on the causes and consequences of people's perceptions of equity and inequity in their relationships with others. First proposed by J. Stacy Adams in 1963 and fully developed in a chapter published 2 years later, equity theory draws on earlier social psychological concepts inspired by Fritz Heider's balance theory (e.g., relative deprivation, cognitive dissonance, and distributive justice). Although equity theory was developed as an approach to explaining the dynamics of social exchange relationships in general, it has been

in the work context that the theory's value was most strongly established.

COMPONENTS OF EQUITY THEORY

According to equity theory, people make comparisons between themselves and certain referent others with respect to two key factors—inputs and outcomes.

- *Inputs* consist of those things a person perceives as contributing to his or her worth in a relationship. In a work setting, inputs are likely to consist of a person's previous experience, knowledge, skills, seniority, and effort.
- *Outcomes* are the perceived receipts of an exchange relationship—that is, what the person believes to get out of it. On the job, primary outcomes are likely to be rewards such as one's pay and fringe benefits, recognition, and the status accorded an individual by others.

It is important to note that the inputs and outcomes considered by equity theory are perceptual in nature. As such, they must be recognized by their possessor and considered relevant to the exchange.

The referent other whose outcomes and inputs are being judged may be either internal or external in nature. Internal comparisons include oneself at an earlier point in time or some accepted (i.e., internalized) standard. External comparisons involve other individuals, typically selected based on convenience or similarity. Equity theory is rather vague about the specific mechanisms through which referent others are chosen.

STATES OF EQUITY AND INEQUITY

In the course of a social exchange with another, or when a person (*P*) and another (*O*) are corecipients in a direct exchange with a third party, *P* and *O* will compare their own and others' inputs and outcomes. A state of *equity* is said to exist for *P* whenever he or she perceives that the ratio of his or her own outcomes to inputs is equal to the corresponding ratio of *O*'s outcomes to inputs. Thus, a state of *equity* is said to exist for *P* when

$$\frac{P's \text{ outcomes}}{P's \text{ inputs}} = \frac{O's \text{ outcomes}}{O's \text{ inputs}}$$

Individuals experiencing states of equity in a relationship are said to feel satisfied with those relationships.

By contrast, a state of *inequity* is said to exist for *P* whenever he or she perceives that the ratio of his or her own outcomes to inputs and the ratio of *O*'s outcomes to inputs are unequal. Inequitable states are purported to result in tension—known as *inequity distress*—and negative affective reactions. The degree of these adverse reactions is said to be proportional to the perceived magnitude of the inequity. Equity theory distinguishes between the following two types of inequitable states:

- *Underpayment inequity* is said to exist for *P* whenever his or her own outcome–input ratio is less than the corresponding outcome–input ratio of *O*—that is, when

$$\frac{P's\ outcomes}{P's\ inputs} < \frac{O's\ outcomes}{O's\ inputs}$$

States of underpayment inequity are claimed to result in feelings of anger in *P*.

- *Overpayment inequity* is said to exist for *P* whenever his or her own outcome–input ratio is greater than the corresponding outcome–input ratio of *O*—that is, when

$$\frac{P's\ outcomes}{P's\ inputs} > \frac{O's\ outcomes}{O's\ inputs}$$

States of overpayment inequity are claimed to result in feelings of guilt in *P*.

MODES OF INEQUITY REDUCTION

Because the emotional reactions to inequity—guilt and anger—are negative in nature, the individuals experiencing them are purported to be motivated to redress them. In other words, they will engage in effort to change unpleasant inequitable states, to more pleasant, equitable states—that is, to redress the inequity. Following from cognitive dissonance theory, Adams has proposed six different modes of inequity reduction, described in the following paragraphs.

Altering One's Own Inputs

If *P* feels overpaid, he or she may raise his or her own inputs in an effort to bring his or her outcome–input ratio into line with *O*'s. *P* may do this by working longer hours (assuming that *P* is a salaried, rather than an hourly paid, employee), by putting forth more effort, and/or by doing work of higher quantity or quality, for example. By contrast, if *P* feels underpaid, he or she may lower his or her own inputs in an effort to match *O*'s outcome–input ratio. *P* may do this by reducing the amount of effort put forth, by working fewer hours (again, assuming that *P* is a salaried employee), and/or by doing work of lower quantity or quality.

Altering One's Own Outcomes

In addition to adjusting one's own inputs (i.e., the numerator of the equity equation), *P* also may adjust his or her own outcomes (i.e., the denominator of the equity equation). If *P* feels overpaid, he or she may lower his or her own outcomes in an effort to bring his or her outcome–input ratio into line with *O*'s. *P* may do this by not accepting a raise or by forsaking an opportunity to move to a larger, more prestigious office, for example. By contrast, if *P* feels underpaid, he or she may attempt to raise his or her own outcomes in an effort to match *O*'s outcome–input ratio. *P* may do this, for example, by seeking and receiving a raise, and/or by taking home company property in an effort to receive a larger share of outcomes withheld.

Cognitively Distorting One's Own Outcomes or Inputs

In addition to making behavioral changes, states of inequity motivate people to cognitively distort their perceptions of their own outcomes or inputs to perceive that conditions are equitable. For example, an underpaid person may come to believe that his or her work contributions are really not as great as previously believed (e.g., he or she is not as well qualified as *P*) or that he or she is more highly compensated than previously considered (e.g., he or she works fewer hours than *P* but is equally paid). Correspondingly, an overpaid person may come to believe that his or her work contributions, in reality, are greater than previously believed (e.g., he or she has more experience than *P*) or that he or she is not really any more highly compensated

than P (e.g., he or she works more hours than the equally paid P).

Leaving the Field

As an extreme measure, one may redress inequity by terminating the inequitable relationship altogether. On the job, this termination may take such forms as seeking other positions within one's existing organization or resigning from that organization entirely. Ending the social exchange functions instrumentally by rendering the social comparison process moot and symbolically by signaling the extent of one's disaffection. Because of its extreme nature, this measure typically occurs only after other modes of inequity reduction have been attempted unsuccessfully.

Acting on the Object of Comparison by Behaviorally Altering or Cognitively Distorting the Other's Outcomes or Inputs

Just as people perceiving that they are in inequitable relationships may change their own outcomes or inputs behaviorally or cognitively, they also may attempt to alter or cognitively distort the outcomes or inputs of others. For example, P may focus on O 's outcomes behaviorally by encouraging O to ask for a raise (if P feels overpaid) or to not accept a bonus (if P feels underpaid), or psychologically, by perceiving that O is, in reality, more highly paid than previously believed (if P feels overpaid) or that O is not actually as highly paid as previously believed (if P feels underpaid). Analogously, P may focus on O 's inputs behaviorally by encouraging O to work fewer hours (if P feels overpaid) or to work more hours (if P feels underpaid), or psychologically by perceiving that O is, in reality, not working as hard as previously believed (if P feels overpaid) or that O actually is working much harder than previously believed (if P feels underpaid).

Changing the Basis of Comparison

According to equity theory, feelings of equity or inequity are based on the specific referent comparisons made. Thus, it is possible for people to feel overpaid relative to some individuals, underpaid relative to others, and equitably paid relative to still another group. For example, a management professor may

feel overpaid relative to philosophy professors and underpaid relative to law professors, but equitably paid relative to other management professors. Simply by switching one's basis of comparison, it is possible for individuals who feel overpaid or underpaid to feel more equitably paid. This underscores the fundamentally perceptual, and not necessarily objective, nature of perceptions of equity and inequity.

Equity theory offers little insight into how people come to select particular inequity reduction mechanisms. It is noted, however, that people favor the least effortful alternatives, thereby making cognitive modes of inequity reduction preferable to behavioral ones. The most extreme reaction, leaving the field, is least preferable.

RESEARCH ASSESSING EQUITY THEORY

The earliest tests of equity theory were laboratory experiments in which participants were led to believe that they were inequitably overpaid or underpaid for performing a task (e.g., they were paid more than or less than expected). The dependent measure was the degree to which participants adjusted their work performance, raising or lowering their inputs, relative to members of control groups who were equitably paid. Such efforts generally supported equity theory. The most compelling evidence came from tests of overpayment inequity, in which it was found that people who were paid more than expected raised their inputs, producing more work than equitably paid participants. Additional research established not only that people respond to inequities as predicted by equity theory, but that they also proactively attempt to create equitable states by allocating rewards to others in proportion to their contributions.

The most recent research inspired by equity theory has been broader in scope and more naturalistic in methodology. Such efforts have found that employees respond to inequities caused by such status-based outcomes as job title and office design by adjusting their performance accordingly. Current research also reveals that employees sometimes steal property from their companies in response to underpayment inequity. In so doing, employees are not only modeling the deviant behavior of their organizations (i.e., stealing in response to underpaying them) but also attempting to even the score by compensating themselves (i.e., raising their outcomes) for payment denied.

THE CURRENT STATUS OF EQUITY THEORY

In the 1980s, organizational scholars recognized that equity theory's conceptualization of fairness in organizations was highly limiting because it focused only on the distribution of outcomes. This disenchantment led industrial and organizational psychologists to follow the lead of social psychologists by broadening their efforts to understand fairness in organizations by focusing on procedural justice. As a result, equity theory is no longer the dominant approach to understanding fairness in the workplace. Instead, it is acknowledged to be only one conceptualization within the broader domain of organizational justice.

ETHICS IN INDUSTRIAL/ ORGANIZATIONAL PRACTICE

Ethics has to do with defining what is meant by *right* and *wrong* or *good* and *bad*, and with justifying according to some rational system what one ought to do or what sort of person one should be. As applied to the practice of industrial/organizational psychology, *professional ethics* concerns the moral appropriateness of our work activities and the proper treatment of all those with and for whom we work, including employees, clients, client organizations and their various stakeholders, interns, students, and professional colleagues. Many of the moral standards that guide such ethical practice are *deontological*, or rule-based in nature, having to do with principles such as the fulfillment of duties and obligations, keeping one's promises, respecting people's dignity and autonomy, maintaining their trust, and striving for fairness or justice. In some instances, determining the proper thing to do seems better understood from a *consequentialist* or *utilitarian* perspective, choosing the action that maximizes the aggregate good or minimizes the net harm resulting from a particular situation.

Most secular ethicists believe neither that there are objectively verifiable moral facts to guide us nor that ethics is merely a matter of one person's subjective judgment versus someone else's. *Ethical reasoning* suggests that the correct ethical choice is the one that is justified by the best arguments. Because it is not possible to specify in advance or to anticipate all of the potential ethical dilemmas one might face, it is advisable to be familiar with some general principles from moral philosophy as well as applicable ethical standards, such as the American Psychological Association's (APA) *Code of Conduct*, that can provide guidance when needed.

THE DOMAIN OF MORAL ACTION

A problem is generally thought to represent an ethical dilemma if it involves the potential violation of one or more fundamental moral or ethical principles such as those enshrined in formal ethical codes such as the APA's. They are as follows:

Respect for people. Deontological moral theories emphasize people's right to be treated with dignity and their rights to privacy or confidentiality, autonomy, freedom, and self-expression. Such rights are *universalizable* (applicable to all) and so do not extend to the point of infringing on the rights of others.

Beneficence. According to this principle, derived from the empathy-based "ethics of care" in moral philosophy, one is expected to do good and promote human welfare when it is reasonably possible to do so. This concept is especially apt when applied to those to whom one has some special obligation or responsibility or who help further one's own interests, such as employees, students, clients, and research participants. It is also especially appropriate for professionals who—by virtue of the authority, influence, and rights society bestows on their profession—are assumed to have societal responsibilities that go beyond serving only their paying clients.

Nonmaleficence. Refraining from unjustifiably doing harm is the principle about which there is most agreement among moral philosophers. It is especially fitting with respect to those in vulnerable positions and extends to guarding against the possible misuse of one's work by others (e.g., misuse of personnel assessments or survey findings). The APA code directs that conflicts among competing obligations be resolved "in a responsible fashion that avoids or minimizes harm" (Principle A).

Fairness and justice. Justice may be defined in a Kantian manner as a balance of rights and obligations. *Social justice* is generally defined in terms of the fairness by which the benefits and burdens of a social system, such as an organization, are distributed among its members. Industrial/organizational psychology has been more concerned with the empirical microlevel question of *perceived justice* than with explicating normative standards of distributive social justice.

Moral virtue or character. This subdomain calls attention to the role of personal qualities in the expression of ethical behavior. It concerns issues such as being sensitive to potential ethical dilemmas and

being motivated to avoid or resolve them fairly, being trustworthy with those with whom one works, accepting responsibility for one's actions, honoring one's commitments, and promoting the accuracy, validity, and integrity of professional work.

An *ethical dilemma* is a problem that implicates one or more of those moral issues and involves having to make a choice that will have a significant impact on the well-being of others.

Types of Ethical Dilemmas

Despite the multitude of potential ethical dilemmas with which one might be faced, most of them can be characterized as falling in one of the following categories—or as a combination of more than one (the categories are not mutually exclusive, in any event).

Foreknowledge of someone to be harmed by a third party. For example, an industrial/organizational psychologist is asked to participate in a process of developing plans for a major reduction in force (RIF) and learns that management does not plan to announce the RIF to employees who may be terminated until the last minute. Senior managers are concerned about possible adverse effects on productivity if it is announced with too much lead time, and the industrial/organizational psychologist is expected to comply with this timetable—which will exacerbate the RIF's harmful effects on those let go.

A self-serving act that will wrong or harm another. The behavior may even be self-serving by proxy—that is, serving the needs of one's employer—and communicated as company policy. Although most managers want to behave ethically, research has indicated that the threshold for unethical behavior is lower when it is perceived as being on behalf of the organization's goals and objectives rather than for personal gain only. For example, it might be tempting to allow management to direct employees' mandatory cooperation with one's data collection efforts even though it should be presented clearly as voluntary, with no consequences for nonparticipation. One might also be tempted to take on a project that is outside one's boundaries of professional competence, as determined by one's education, training, study, and supervised or professional experience.

Competing obligations to two or more entities. Every good supervisor or manager has encountered situations in which it may not be easy to be fair

and impartial to all employees in the distribution of organizational rewards or with respect to other personnel decisions affecting subordinates. Industrial/organizational psychologists often face analogous conflicts by virtue of our simultaneous obligations to both the client organization (or employer) and the individual employees and managers with whom we work. A review by Carolyn Wiley of the codes of conduct of five professional human resources organizations revealed uniform acknowledgment of multiple obligations to the public or society at large, the employer or client organization, employees, and colleagues and to one's profession and professional association. When working with individuals or teams (e.g., in executive coaching, conducting focus groups, individual assessment, or organizational diagnosis), it is advisable to clarify beforehand and explain to those individuals or groups one's obligations to the organization, such as any necessary limitations on anonymity or confidentiality.

A situation in which two or more equally important ethical values conflict. For example, if an anonymous survey respondent alleges some serious wrongdoing by a senior manager who is putatively damaging the company, the industrial/organizational psychologist has to choose from among courses of action (which include doing nothing) that balance conflicting obligations to respect employee anonymity, to avoid harming a potential victim of mere gossip, and to prevent possible further damage to the organization. The most appropriate response is likely to be determined by details of the situation.

Pressure to violate ethical principles. Business corporations, and the managers who run them, are not subject to all of the ethical standards that characterize the professional responsibilities of psychologists, who are obliged by the preamble of our ethical (APA) code to use knowledge to better people and organizations. The managers are, in fact, subject to pressures for productivity, efficiency, speed, and profitability, and these aims may at times be at odds with some ethical standards. For example, a senior manager might wish to use, for purposes of making personnel decisions, assessment or survey data that had been obtained confidentially after explaining to all participants that it would be used only for personal development or organizational improvement. Standard 1.03 of the APA code also indicates that if there is conflict between the ethical code and organizational demands, the psychologist must resolve the conflict in accordance with the code.

Determinants of Ethical and Unethical Behavior

The expression of ethical behavior (i.e., its incidence and form) can be explained by four general categories of antecedents:

Cultural influences. These include social, economic, and political factors that influence the development of ethical norms and practices through the institutions of a society. For example, in Western (especially American) free-enterprise capitalist society, social justice or fairness is generally understood in terms of *merit*, which is defined by the distributive justice criterion of *equity*, as opposed to *equality* or *need*. Moreover, equity itself is conceived within an individualistic perspective, whereas in many other parts of the world a *communitarian* standard is viewed as right. These ideas consequently shape our values regarding the proper definition and meaning of constructs such as *test bias* and *test fairness*. The socialization experiences that shape one's standards of conduct are initiated and/or mediated by family, schools, peers, religious training, employer organizations, and other institutions.

Individual difference variables. Interdisciplinary research in *moral psychology* has shown that early cognitive and emotional development (e.g., the development of *empathy*) underlies moral development. Adults differ in attributes that fall within the conception of *moral character* or *virtue*—traits such as honesty, moral values, moral sensitivity, moral imagination, moral motivation, and moral self-identity. One's values determine, in part, whether one even experiences a particular situation as an ethical dilemma or choice. For example, some psychologists refuse to work for a cigarette manufacturer; others see nothing wrong in furthering the fortunes of a legal enterprise; still others may consider the situation in terms of a balance of benefits and harms.

Attributes of the dilemma. The relative difficulty and upset caused by an ethical dilemma is a function of its moral complexity, moral intensity, and other factors. *Moral complexity* pertains to the number of moral values and principles evoked and the relations (e.g., conflict) among them. *Moral intensity* is determined by the degree of social consensus surrounding the ethical issue, the nature and magnitude of the decision consequences for those affected, and the likelihood of those consequences occurring. Also relevant are who is likely to be benefited or harmed and, in

the case of organizational settings, how public the situation is.

Contextual, including organizational, influences. Situational effects on behavior constitute a long-standing topic in social psychology. In this domain, for example, ethical judgments have been shown to be influenced by whether one is primed to identify with the perpetrator or the victim of a moral transgression. In the organizational setting, ethical norms, behavior, and the perception of unethical behavior have been shown to be influenced by one's position and status in the organization and by the organization's *ethical culture*, as reflected in the relative salience of moral standards, its social sanctions and reward structure, and the modeling of senior managers and supervisors (the "tone at the top"), as well as the absence of *counter-norms* that contradict the ethical culture (e.g., pressure to "do whatever it takes to get the job done").

PREVENTING ETHICAL PROBLEMS

Although it is impossible to foresee all the ethical dilemmas one might encounter, some activities can help one to anticipate likely problems and ready oneself for thinking through them when they arise.

1. Be familiar with the applicable ethical codes such as those of the APA, the Canadian Psychological Association, the Academy of Management, the International Personnel Management Association, and the Society for Human Resource Management. Also know applied sources and articles such as the Society for Industrial and Organizational Psychology's ethical case book, edited by Rodney Lowman. The introduction of the APA code states explicitly that ignorance of ethical standards is not a defense against ethics charges.
2. Be familiar with applicable state laws and federal regulations. These include laws regulating the licensing of psychologists and dealing with issues of confidentiality, malpractice, and research with human participants. Especially pertinent are statutes and regulations governing employment practices, such as the Civil Rights Acts of 1964 and 1991, the Americans With Disabilities Act, the Age Discrimination in Employment Act, and the *Uniform Guidelines on Employment Selection Procedures*.
3. Know the rules and regulations of the institution at which you work. This knowledge helps assure competent practice in keeping with the organization's expectations and can alert one to possible conflicts

between organizational norms and professional ethical standards.

4. Engage in continuing education in ethics by means of attending courses and workshops, reading books on ethics and ethical practice, and subscribing to relevant journals such as *Ethics and Behavior*, *Professional Psychology*, *Journal of Business Ethics*, *Business and Society*, and *Business Ethics Quarterly*.
5. Attempt to identify areas of potential ethical difficulty before a problem arises. That identification will be aided by information gleaned from the preceding four activities.
6. Maintain a mind-set of ethical watchfulness. In addition to the previous steps, one can exercise one's moral sensitivity to avoid ethically ambiguous situations or attempt to clarify them before becoming involved.
7. Learn a systematic approach for analyzing ethical problems in complex situations. Many texts on applied ethics contain decision-making models for this purpose. The one presented by Joel Lefkowitz is in the context of industrial/organizational psychology. Perhaps most important, find a trusted and knowledgeable confidant with whom to share your concerns. Ethical dilemmas can be very stressful; it is best to not go through the process in isolation.

—Joel Lefkowitz

ETHICS IN INDUSTRIAL/ ORGANIZATIONAL RESEARCH

Ethics has to do with defining what is meant by *right* and *wrong* or *good* and *evil* (or *bad*) and with justifying according to some rational system what one ought to do or what sort of person one should be. As applied to the conduct of research with human participants, the ethics of research concerns the proper treatment of those participants—their protection—by researchers. This overlaps with, but is different in intent from, the ethics of science, which has to do with the protection of the scientific enterprise by means of norms concerning ways in which its integrity is maintained (e.g., providing full and accurate descriptions of procedures in published research reports).

Deontological (i.e., rule-based) moral principles generally guide the ethical strictures concerning research participation: treating people with dignity and respect for their autonomy (so they are free to decide whether to participate in the research and whether to continue their participation); having concern for their well-being and avoiding the infliction of harm (so that if deception or withholding information can be justified by a rigorous review, adequate debriefing and dehoaxing will be provided); abiding by principles of justice or fairness (so that people are not coerced into participation by virtue of their lesser social status or other factors); and displaying honesty, integrity, and trustworthiness (so that promises made regarding the confidentiality of replies and the potential benefits, discomforts, or risks of participation are fulfilled). However, consequentialist or utilitarian analyses are frequently used in deciding whether the aggregate benefits of a proposed research study outweigh any potential harms involved.

THE NATURE OF INDUSTRIAL/ ORGANIZATIONAL RESEARCH: WHO BENEFITS?

Most research in the social and behavioral sciences is not conducted to benefit those who participate in it as sources of information. Some studies seek to advance our general understanding of psychological processes or constructs (e.g., “What are the determinants of organizational citizenship behavior?”). The students or employees from whom we hope to learn the answers to such questions may have little interest in

the questions or the research and cannot expect to benefit from it. Even much of the applied research that aims to improve the functioning of the organization in which it is implemented is unlikely to improve the welfare of those particular research participants (e.g., applicants or employees in a test validation study). Nevertheless, some organizational studies are of the sort that will yield benefits for the organization as a whole as well as for the participants (e.g., an experimental evaluation of alternative training procedures, the best of which may then be implemented to the benefit of all). And some organizational research activities are components of what might more accurately be described as *interventions* (the introduction of changes in policies, programs, or practices) that are directly aimed at improving aspects of the work life of some segment of the organization.

Therefore, potential research participants, even company employees, should not be thought of as necessarily being obliged to cooperate with one’s research plans. That is one of the important reasons why much of the ethics of research has to do with the appropriateness of the conditions under which prospective research participants are recruited and the voluntariness of their agreement to participate. Other reasons similarly involve basic ethical principles such as respect for persons—their inherent dignity and autonomy—and issues of justice. The essentials of ethical research consist of assuring voluntary participation and informed consent to participate; eliminating coercive influences; securing privacy and confidentiality for participants; minimizing the deception of participants; and providing debriefing, feedback, and *dehoaxing* (correcting any adverse effects of deception). These concerns are codified and operationalized in the U.S. Department of Health and Human Services (DHHS) Federal Policy for the Protection of Human Subjects and the American Psychological Association (APA) Ethical Principles of Psychologists and Code of Conduct.

THE HISTORY OF RESEARCH REGULATIONS

Applied psychologists such as Allen J. Kimmel and other social scientists working under the auspices of the National Research Council have traced the events that led to a growing concern for the protection of participants in biomedical, social, behavioral, and economic sciences research in the 30 years following the end of World War II. These are some critical events:

- At the end of the war, the world was repulsed when it was learned that bona fide medical doctors had been conducting gruesome and horrific experiments on concentration camp inmates.
- For 40 years, beginning in 1932, the U.S. Public Health Service Tuskegee Study withheld treatment for syphilis and deceived almost 400 Black men about the (non)treatment they were receiving, resulting in up to 100 deaths by 1969. Treatment was not provided until after the experiment was uncovered in a 1972 newspaper report.
- In the mid-1950s, in the Wichita Jury Study, law professors secretly recorded the deliberations of several juries without the knowledge of the plaintiffs, the defendants, or the jurors themselves.
- In the early 1960s, a social psychologist, Stanley Milgram, tricked his research participants into believing that they were administering stronger and stronger electric shocks to subjects (actually, Milgram's confederates) when they responded incorrectly in a "learning experiment." A majority of participants remained obedient to the experimenter even when the learners supposedly being punished were apparently in considerable pain and they themselves were experiencing great discomfort and ambivalence about what they were ostensibly doing.

In 1946, the modern era of biomedical research oversight was ushered in by the Nuremberg Code, whose 10 principles emphasize that participation in experimental research must be voluntary, participants must be free to discontinue their participation, and the possibility of harm and risks must be minimized and exceeded by the potential beneficial findings of the experiment. At about that same time, the APA also was deliberating standards of ethics, including issues pertaining to psychological research, resulting in a formal statement of Ethical Principles of Psychologists and Code of Conduct in 1953, which has been revised several times—most recently in 1992 and 2002.

It is not clear, however, that research psychologists (and other social scientists whose disciplines had also developed codes) paid all that much attention to their ethical standards of research until the federal government began to take several larger and larger steps into the picture. In 1966 the United States Public Health Service (USPHS) required that federally funded medical research facilities had to establish review committees (the first institutional review boards, or IRBs) to pass on proposed research; in 1969 the policy was extended to include behavioral and social science research. These policies were further developed by

the Department of Health, Education and Welfare (DHEW) in 1971 (The Institutional Guide to DHEW Policy on Protection of Human Subjects) and 1974 (45 Code of Federal Regulations [CFR] 46). In 1979, the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research produced Ethical Principles and Guidelines for the Protection of Human Subjects of Research ("The Belmont Report"). It placed research with human subjects firmly within a moral framework by emphasizing the relevance of three ethical principles: respect for persons (acknowledging their autonomy and protecting those with diminished autonomy); beneficence and nonmaleficence (the obligation to maximize possible benefits to participants and to do them no harm), and justice (fairness in the distribution of the benefits from, and burdens of, research). In 1981, the National Institutes of Health (NIH) Office for Protection From Research Risks (OPRR) revised 45 CFR 46. Finally, in 1991 the Department of Health and Human Services (DHHS, the successor to DHEW) published a further revision (45 CFR 46, subpart A) that was adopted as "Common Rule" by all relevant governmental agencies and applied to all research conducted at institutions that receive any federal funding. In 2000, the Office for Human Research Protections (OHRP) was established in DHHS, with expanded educational responsibilities as well as regulatory oversight.

From 1966, there has been almost continuous criticism by the social and behavioral sciences research community of the regulatory process conducted by the IRBs that pass on the acceptability of proposed studies. These complaints and the administrative reactions to them, as well as several national investigations of the operation of IRBs, have resulted in a cyclical waxing and waning of the scope and relative restrictiveness and permissiveness of the successive revisions to the regulations. The most frequent complaints have been (a) lack of consistent standards of evaluation across IRBs; (b) lack of expertise among IRB members to evaluate proposals from many different disciplines; (c) greater concern for the bureaucratic formalities of signed consent forms than on furthering prospective participants' understanding of the proposed research; (d) inappropriately critiquing technical aspects of the research design rather than limiting the review to the protection of participants; and (e) failure to take advantage of the flexibility built into the Common Rule—for example, by requiring full board review rather than expedited review or even an exemption from review for

minimal risk research (studies, like most of those in industrial/organizational research, that entail procedures no more risky than ordinary life activities or routine physical or psychological tests).

CURRENT REGULATIONS

An IRB review of proposed studies begins with consideration of four sequential questions:

1. Is it research? According to the Common Rule, *research* is an investigation intended to expand or supply generalizable knowledge. Projects (e.g., attitude surveys, test validation studies) intended for internal organizational use are not included, but if findings are submitted for publication, that would be an attempt to contribute to generalizable knowledge. (IRB approval might be possible ex post facto for the now archival data if it is anonymous.)
2. Does it involve human participants? Such involvement means obtaining private information from living persons who may be individually identifiable. This would exclude qualitative and quantitative literature reviews that are limited to secondary analyses of aggregate data.
3. Does it fall into one of the categories of research exempt from IRB review? The IRB (not the researcher) can determine that the proposed study does not require review. This includes such projects as evaluations of instructional strategies in educational settings, and the use of survey and interview procedures or the collection of existing data—as long as the respondents cannot be identified.
4. If not exempt, does it entail no more than minimal risk so that it is thus eligible for expedited review? Under expedited review, only the IRB chair (or designee) reviews the study, rather than the full board, and the study cannot be disapproved (only the full board can do that). This category includes individual or group behavior research or characteristics of individuals—for example, perception, cognition, game theory, and test development—in which the subjects' behavior is not manipulated and research does not involve stress on the subjects.

BASIC COMPONENTS OF ETHICAL RESEARCH

Privacy, Confidentiality, and Informed Consent

People have a right to maintain their privacy—that is, the right to determine how much information about

themselves will be revealed to others, in what form, and under what circumstances. Empirical research indicates that perceived violations of privacy depend on the nature of the information being sought, how public the setting is in which a person's behavior is being studied, people's expectations regarding privacy, and the anonymity of the research data—that is, assurance that the data cannot be linked directly to the respondent source. It probably also depends on the degree of trust in which the researcher is held by participants. *Confidentiality* refers to people's right to have the information they provide kept private, as well as to the agreements made with them regarding what will be done with the data. Establishing conditions of anonymity is the best way to guarantee privacy and complete confidentiality. Most of the time, a psychologist's research participants (e.g., employees or students) will assume that the information they provide is to be kept confidential. Therefore, it is imperative that any limitations on confidentiality be explained carefully in advance of securing the person's participation. For example, studying the determinants of voluntary employee turnover may require maintaining the identity of data sources so that antecedent information can be linked with later separation data. This should be explained to potential participants, and the personal identifiers that provide the link should be destroyed once the matching is done.

Describing to prospective research participants any limitations on confidentiality is part of the information to be supplied prerequisite to obtaining their informed consent to participate. To summarize briefly the Common Rule and the APA ethics code (Standards 3.10, 8.02, 9.03), additional information to be provided in clear, unambiguous, readily understandable language includes the purpose and expected duration of the research, and its procedures; any factors that might reasonably be foreseen to affect a person's decision to participate; the participant's right to decline to participate or discontinue participation, along with any consequences for not participating; and whom to contact with any questions about the research or the participant's rights. Opportunity should also be provided for the person to have any questions about the research answered. Although obtaining a signed consent form containing the above information from each participant is the default option, there are a number of circumstances under which a waiver can be granted under the Common Rule. These include minimal-risk research; studies of

educational programs; routine assessments of organizational practices; archival data; and collecting test, survey, or interview data—as long as participants cannot be identified; for studies that could not be done unless the waiver was granted; and when the signed consent form would be the only record linking the respondent with the research and a breach of confidentiality would be potentially harmful (e.g., an employee survey of admitted unethical behavior).

The Use of Deception

When individuals are misled (active deception) or not told (passive deception) about significant features of the research in which they are being asked to participate, it arguably violates the principles of respect, autonomy, and trust underlying the researcher–participant relationship and the spirit and intent of providing informed consent. Consequently, deception has been an extremely controversial practice in social science research—much more prevalent in social psychology than in industrial/organizational psychology, owing to differences in the topics studied and the preeminent use of laboratory versus field studies, respectively. The most common forms of deception are concealing the true purpose of the study and/or aspects of its procedures by giving participants false instructions or false information about stimulus materials, use of a confederate to mislead them, and providing erroneous or manufactured feedback about their performance on some task.

Although critics such as Diana Baumrind argue that deception is never justified because of the long-term potential harms it inflicts on participants, on the reputation of the profession, and on society, deception is generally viewed as conditionally appropriate. For example, the APA ethical code indicates that it may be justified by the potential significant value of the study, if the research question cannot be investigated effectively by nondeceptive means, and as long as the deception is explained promptly to the participants and any misconceptions induced in participants are corrected. It is extremely unlikely, however, that any substantial deception would be viewed as appropriate in industrial/organizational research conducted with employee participants in an organizational setting.

EUSTRESS

The Canadian physician Hans Selye was first to define *stress* as the response to stressors in the environment. He considered *stressors* to be the external demands or influence an individual feels at any given time. Selye separated stress into two categories: *distress* and *eustress*. Distress occurs when there is too much or too little demand on an individual and disrupts homeostasis. Too much stress can cause performance to decline, whereas no stress at all may cause an individual to lack the motivation and energy to perform. When stress is at a moderate level, it supplies the individual with enough energy to accomplish high levels of performance. During this optimal level of arousal, eustress is believed to occur, which is why eustress is commonly referred to as *positive stress*. Unlike negative stress (distress), eustress is believed to have benefits to the body and mind. These include increased mental alertness and awareness and improved emotional and physical well-being.

In addition, Bret Simmons and Debra Nelson found that when employees experience eustress, they

will be more likely to have a positive perception of their own health.

Selye believed there are ways for people to experience more eustress and less distress by changing how they perceive and react to their stressors. He suggested that having more positive or optimistic views of stressors will increase eustress, performance, and overall health (i.e., lowered blood pressure, less depression, and less susceptibility to diseases). Research indicates that eustress is positively correlated with employees' level of job satisfaction and causes less turnover. Supervisors can promote eustress among employees by setting realistic goals and deadlines for projects, by giving appraisals and encouragement to employees, and by displaying positive, calm reactions of their own during times of difficulty.

EXECUTIVE COACHING

Executive coaching is an increasingly popular and important part of overall executive development in the United States, Europe, and elsewhere. At the present time, large numbers of people say they do executive coaching, representing a wide range of kinds and levels of knowledge bases, competencies, and credentials—including psychology, engineering, philosophy, anthropology, education, economics, English, communications, and library science (and even no college degree). At this writing, there are no universally recognized and accepted standards for practice, and definitions of executive coaching vary.

In the past 10 to 15 years, however, the practice of executive coaching by psychologists has become more defined and has gained considerable momentum, and a

distinct body of knowledge from practice and recent research is being developed and shared. This piece pertains to executive coaching by psychologists.

DEFINITION

The following definition is consistent with most of the working definitions found in the existing psychological and management literature and in presentations at professional conferences: executive coaching is an *individualized* process of executive development in which a skilled expert (coach) *helps* an individual who is in a leadership or managerial role in an organization *learn* how to become more *effective* in that organization and/or in those kinds of roles. Italicized terms are key. Coaching is a helping relationship between a coach and coachee, one-on-one. It is a process, as opposed to a fixed-curriculum program such as training or group executive development programs, and is designed specifically for the coachee. Some coaches refer to the process as a “journey” of discovery, learning, and change. As the process unfolds, and as the coach and coachee learn more, the course (path) is adapted or modified to best meet the goal(s). The coachee’s overarching goal is to become more effective, and the primary enabling objective is the coachee’s learning.

Although coaching is a key responsibility of every manager who supervises employees, executive coaching, as discussed here, pertains to the role of a third-party (i.e., not the coachee’s supervisor) professional psychologist coach.

HISTORY OF EXECUTIVE COACHING

Consulting by psychologists to organizational leaders has been around for a long time—at least since the 1940s—and the name *executive coaching* to describe it emerged in the late 1980s. This practice area has seen what many describe as explosive growth over the past decade, because of significant popularity and widespread demand.

The vast majority of the research to date has been conducted in the past 15 years and is primarily practice-based, with case studies being the most common method. Although little empirical research on outcomes has been published to date, there is evidence of increasing focus on coaching by scientific researchers, with several studies recently published and in progress.

NATURE OF EXECUTIVE COACHING BY PSYCHOLOGISTS

The practice of executive coaching spans a number of areas of psychology, including clinical, counseling, industrial/organizational, developmental, and social psychology—all represented in consulting psychology. Because executive coaching is a one-on-one helping relationship, clinical and counseling psychology have contributed the most in terms of typology of coaching methods; the principles, art, and ethics of working with individuals; and associated research methods. Industrial/organizational and social psychology contribute significantly in organizational theory, work motivation, interpersonal dynamics, social-organizational dynamics, psychometric theory, assessment, organizational development methods (applied one-on-one), and meta-analysis of outcomes. Coaching draws from developmental psychology for principles of adult learning, stages and characteristics of adult development, and maturation.

Common Characteristics

- Content and process are tailored to the individual's needs.
- Confidentiality is strictly maintained, to enable free discussion of sensitive issues in a safe environment.
- The coach typically uses a wide variety of methods and tools (see "Typical Methods and Tools"), with varying degrees of structure, to help the individual achieve the coaching goals.
- Psychologist coaches focus primarily on cognitive, behavioral/interactional, and/or emotional aspects of performance effectiveness.
- A fundamental assumption is that by enhancing the leader or manager's effectiveness, the effectiveness of the organization is also improved, via the influence and leverage of leadership.

Examples of Differences in Views Across Psychologist Coaches

- Coaching as a dependency relationship or not
- Coach role to provide advice, direction, counsel versus to facilitate a process of self-discovery and learning
- Coaching method(s) used

Typical Areas of Coaching Focus

Executives seek assistance from executive coaches primarily for the following purposes:

- For skill development (e.g., leadership, interpersonal, organizational, intrapersonal)
- For performance enhancement—current job
- For development—for future roles
- To have a sounding board for testing thinking, surfacing assumptions, uncovering blind spots, obtaining objective feedback, and so forth
- For proactive/developmental and/or remedial help—to address one or more problematic behaviors

INTERVENTION APPROACHES AND THEORETICAL ORIENTATIONS

Consumers of executive coaching services are primarily senior managers and executives, or identified high-potential managers, who have already demonstrated a high degree of success. Thus, the focus is nearly always on helping already successful people become more so—for example, helping them get to the next levels of effectiveness, preparing them for advancement, or helping them quickly adapt to a new role. For them, group methods, such as executive education courses, reach a point of diminishing returns, and further gains will come only from intense personal focus and work. Also, a not insignificant proportion of executive coaching clients seek help in changing one or more problematic behaviors that are limiting their effectiveness and potentially their career progress.

The most common intervention approaches and related theoretical orientations of psychologist coaches are *behavioral*, *cognitive-behavioral*, *rational-emotive behavioral coaching*, *psychodynamic*, and *multimodal*. These are adapted to coaching from clinical therapeutic models. In the behavioral approach, the focus of the coaching intervention is behavior. The coach works to help the individual understand the impact of his or her behavior; to further refine and effectively leverage behavioral strengths; to learn new, more effective behaviors; and/or to manage weaknesses. Progress is tracked, and reinforcing mechanisms are typically implemented for sustained improvement. In the cognitive-behavioral approach, the coaching intervention is targeted at thought processes and/or behaviors, using any of a wide range of intervention strategies. Assumptions are as follows: (a) One's thoughts about events affect behavioral response to those events; (b) thought patterns can be accessed, monitored, and modified; (c) changes to thought patterns can change behavior in desired ways; and (d) changed behaviors can eventually change thoughts. Because executive

coaching is results-driven, with emphasis on measurable improvement, this is a common approach. Its limitations are seen primarily in those cases where deeper emotional, internal conflict or object relations issues are the primary factors affecting performance.

Rational-emotive behavioral coaching is a special type of cognitive-behavioral intervention. Its assumptions are as follows: (a) Emotional and behavioral responses to events are shaped by one's interpretation of those events, and interpretations are influenced by one's beliefs, which are sometimes irrational; and (b) if people can be helped to eliminate irrational beliefs (e.g., absolute thinking, catastrophizing), they can direct their energy toward achieving their potential. Coaching is directed at challenging and changing behaviors that negatively influence effectiveness.

In the psychodynamic approach, intervention is focused at a deeper psychological level. Assumptions are that unconscious factors, including past experience, emotional responses to events, defensive reactions, suppressed feelings, underlying and unresolved conflicts, and various dysfunctional patterns of thinking and behaving, can negatively affect performance and organizational effectiveness. Specifically applied to coaching, assumptions include the following:

- Internal unconscious conflict produces strong emotions that people work to keep out of conscious awareness because of associated discomfort. The self-protective behaviors they engage in to suppress these emotions can themselves cause problems interpersonally, as well as intrapersonally in the form of anxiety, depression, stress, and other conditions that affect performance.
- One's effectiveness in work relationships is influenced by one's history of development and past relationship experiences.
- Recognizing and understanding psychodynamic processes at work can help the coach develop much more effective interventions.
- Last, *multimodal* refers to the use of more than one intervention approach.

DIFFERENCE BETWEEN COACHING AND THERAPY

Executive coaching is quite different from clinical therapy, the differences being primarily the focus and depth of the intervention. Therapy focuses on internal unresolved conflicts and/or object relations issues, delving deeply into unconscious motives and past

experiences and relationships. Executive coaching focuses on individual effectiveness in leadership roles, working in the present and at the level of primarily conscious awareness. To the extent that unresolved conflicts or other pathology are interfering with performance, the coach will make a referral to a qualified therapist for the necessary deeper-level work.

IMPORTANT COACH COMPETENCIES

The coach is the most important tool in helping the coachee achieve the coaching goals and is integral to the process of learning and changing. Key coach competencies include the following:

- *Knowledge.* Especially important are advanced knowledge of psychology of behavior in organizations; knowledge of organizational theory; business knowledge; knowledge of the client's organization and industry; knowledge of the ethics code for psychologists; and self-knowledge.
- *Skills.* Especially important skills include cognitive agility; listening; systems thinking and practice; communication; (desirable) psychological assessment; process facilitation; connecting with the individual; and gaining and maintaining trust.
- *Personal characteristics.* Important personal characteristics include being an agile learner; perceptiveness; flexibility; nonjudgmentality—being accepting of people and their values; tolerance of ambiguity; political savvy; trustworthiness; respectfulness of others as people; and appreciativeness of the coachee's talents.

TYPICAL REFERRAL SOURCES

Typical coaching referral sources are as follows:

- Self (often referred by someone who has benefited from and recommended coaching)
- Supervisor
- Human resources

TYPICAL PROCESS

Although approaches vary, they all tend to have a similar general process:

- Request for coaching, and selection of the coach
- "Contracting"—that is, aligning expectations; establishing rules of engagement; agreeing on who the

client(s) is/are; and agreeing on the approach, timing, fees, and so forth

- Assessment of need, including understanding the individual and the context in which performance occurs; and identifying performance strengths, limitations, and development needs. Assessment involves collecting data—existing and new. Examples include the following:
 1. Existing information such as performance appraisals; 360-degree feedback; assessment reports from previous management development programs; and other relevant information, including key e-mail messages
 2. In-depth interview of coachee
 3. (Optional) Individual professional assessment, which may include any subset of measures of cognitive ability and problem solving; personality; emotional intelligence; needs; values; leadership style; interpersonal style; and other relevant organizational effectiveness factors
 4. Information produced from the coachee and from coach-coachee interactions
- Development of coaching goals
- Intervention (coaching) plan
- Implementation of the coaching plan
- Measurement of progress

TYPICAL METHODS AND TOOLS

Typical coaching methods include (a) the use of a coaching plan, including objectives, success criteria, and associated measures, as well as (b) face-to-face meetings. Other methods are telephone conversations between meetings, individually designed exercises, and assigned readings.

Tools may include the following:

- Facilitating thinking, surfacing of assumptions, gaining insight
- Educating, explaining
- Reframing of issues, events, thinking
- Challenging while personally supporting
- Confronting while personally supporting
- Suggesting
- Tailored exercises to facilitate thinking, working through issues, and/or gaining insight
- Role playing
- Other—depending on the situation and need

TYPICAL DURATION

The duration of coaching varies widely—from a few months to many years. Coaching that lasts more than

a year usually evolves into more of a “trusted adviser” relationship.

CERTIFICATIONS

Certifications are offered by several different organizations, most requiring minimal prerequisites, and none of which are sanctioned by the American Psychological Association, and by a few academic institutions that offer executive coaching as a continuing education or executive education program.

EXECUTIVE SELECTION

Executive selection represents an important means of gaining competitive advantage for today's organizations. However, such selection has not traditionally used the rich history of conceptual and empirical research on personnel selection that exists within the domain of industrial and organizational psychology. The high failure rate of today's executives points to the need for more effective selection of top organizational leaders, and there has been a recent upsurge in research and development focused on sharpening knowledge and practices of executive selection.

In 2001, Ann Howard described four central topics reflect key issues in executive selection. The first issue refers to executive competencies that ought to guide the process of executive selection. These competencies are necessarily broader and more complex than those for lower- and middle-level organizational leaders. The second issue refers to the source of executive candidates, whether they come from within the organization or are recruited from external sources. The third issue pertains to the assessment strategies used to uncover levels of competencies in executive candidates. The final issue covers the actual selection decision, particularly who makes this decision and how the decision-making process reflects and influences organizational strategy.

EXECUTIVE COMPETENCIES

Research has shown that performance requirements change significantly as leaders rise to the executive level. They need to attend to and interpret a vastly greater array of information. Their constituencies and stakeholders become more diverse, with more conflicting agendas. Although all leaders are responsible for monitoring and spanning the boundaries of their unit and the larger environment, leaders at the top must represent the organization to an external environment (and vice versa) that is increasingly complex, global, and dynamic. Thus, although all leaders in an organization are responsible for setting the direction and managing the operations of their units, these characteristics of executive work define some particular competencies for top organizational leaders that need to guide their selection.

The responsibility for leading a diverse organization and representing it within the industry suggests that executives need broad technological, financial, and

professional knowledge, as well as an understanding of the industry and its operating environment. The high informational complexity of executive work means that they need to have the cognitive skills to make sense of and model this complexity for their subordinates. Executives also need high-level social competencies, including communication skills and the ability to develop broad social capital or a network of personal relationships that accrue trust, information exchange, normative expectations, and professional knowledge. Executives need to have the skill to develop these networks of social capital within and across organizational boundaries. Finally, given the highly dynamic industry environments of most organizations, executives also need an array of skills linked to an ability to manage change for themselves and for their organizations.

EXECUTIVE RECRUITMENT

Executive recruitment can focus exclusively within an organization or on external sources of executive candidates. In her 2001 review of executive selection research, Howard notes several advantages and disadvantages for both internal and external executive recruitment have advantages and disadvantages. Internal recruitment strategies link executive development with executive selection, providing a long-term growth perspective for lower-level managers. When executive development is systematic and tied to changing strategic considerations, the company can enhance its strategic flexibility and generate a pool of candidates particularly well suited to implement strategic changes. Internal candidates already have knowledge of the organization's culture and structure and already have the established social capital to quickly implement new initiatives. Internal recruitment can also engender greater loyalty and commitment to the organization among its lower-level managers.

Howard has also noted that internal candidates may be too associated with organizational culture and norms to provide new and fresh approaches. External candidates can bring different experiences, new industry knowledge, and novel perspectives to the organization. Their evaluations of existing organizational policies, structure, and projects are likely to be more objective than those of internal candidates. Likewise, although external candidates will have less social capital within the company than their internal brethren, they may have broader capital outside the company, enhancing their ability to form industry alliances and networks.

The choice of an internal versus external candidate may rest on the prior performance of the company, its age and growth pattern, and the dynamism of the industry's strategic environment. In larger companies, and Generally, internal candidates are likely to be favored when the organization is performing well, when the company is established and maintaining a slow but steady growth rate, and when the rate of change in the strategic environment is not fast enough to render skills and knowledge too quickly obsolete. Alternatively, external candidates are likely to be favored in companies that are performing poorly, in young companies experiencing a high rate of growth, and in organizations where greater numbers of external members sit on the board of directors. Preferences for external candidates also may occur when change rates in industry environments require rapid upgrading or refreshing of leader human capital. In typical instances, however, the circumstances of most organizations will suggest a varying mix of internal and external candidates for the range of executive positions.

External recruitment sources include executive search firms, electronic or Internet-based searches, and personal networking. In 1998 Daniel DeVries noted that executive search firms aid executive selection by facilitating the process for both potential candidates and hiring firms. Search firms will help companies define position responsibilities and corresponding candidate competencies. They will also recruit and identify candidates who best fit position characteristics. Executive search firms can help candidates understand the dynamics within the hiring company and coach them through several critical stages of the selection decision process. Many executive search firms, as well as human resource departments in major corporations, use the Internet as a source of executive recruitment. Although the canvassing of active candidates may occur through job boards, companies and search firms may use searches of company records and online directories to identify candidates who are not actively searching for new executive positions but may be approachable or persuaded to consider a position change. A third strategy of executive recruitment is for existing company executives to pursue their social networks and personal contacts for executive position candidates.

Internal executive recruitment generally rests on the succession planning and executive development programs established by companies to grow the pool of high-potential executives. If development programs are linked to the anticipated strategic considerations of the organization, they can produce a strong pool of

potential candidates. Even when strategic concerns are likely to shift (as when the company operates within a dynamic organizational environment), executive development that emphasizes the ability to manage change and uses a breadth of developmental experiences can produce sizable numbers of suitable candidates.

EXECUTIVE ASSESSMENT

Some strategies used to assess candidates for lower-level managerial positions have been extended to executive selection, although with limited success. For example, assessment centers, used with mixed effectiveness in lower-level managers, have been used less extensively with executives. However, research has shown ratings of managerial potential, established in part through assessment centers and structured interviews, have predicted long-term promotion levels, including to executive ranks. Executive assessment strategies have focused on identifying the candidate's past performance effectiveness and the human capital and competencies a candidate can bring to the position. Some assessment approaches examine how well the candidate might handle simulated executive work situations.

Companies typically assess past performance effectiveness through biographical data (résumés), references, structured interviews, and, in some instances, multisource surveys and interviews (in which data come from peers, supervisors, subordinates, and self). Each of these strategies carries some strengths and weaknesses. Biographical data sources and references can exhibit a positive bias and achievement inflation. Interviews can also result in positive image management by the candidate. However, structured interviews that ask candidates to describe past critical incidents and key performance episodes have yielded more success in identifying the candidate's displayed competencies. In her review Howard noted that multisource assessment can be more effective when source ratings are coupled with interviews conducted by executive coaches. Using measures of past displayed competencies can be problematic for executive selection, though, when strategic considerations argue for new or different sets of executive competencies.

Companies also use a range of individual difference measures to assess the personal qualities candidates possess at the time of recruitment. Measures of conceptual capacity, cognitive ability, and tacit knowledge have exhibited some success in predicting executive performance. Companies have also used personality measures

in their executive assessment. Taken together, these measures can provide a significant although still limited prediction of likely executive success.

Another assessment strategy involves presenting executive candidates with simulated executive leadership scenarios and observing exhibited behavior and decisions. These simulations and work sample tests, typically organized as part of an assessment center, have the advantage of measuring present competencies and, if carefully structured, can provide an assessment of how executive candidates would respond to performance scenarios dictated by future or alternate strategic considerations.

Most companies use a combination of methods to assess executive candidates, although interviews and references remain the most prominent assessment strategies. Cognitive ability, personality, multisource assessment, and assessment centers are less widely used for executive selection. However, such assessments constitute a significant part of executive development programs used to produce succession pools of internal candidates.

EXECUTIVE SELECTION DECISIONS

The capabilities of the executive candidate represent one factor in the selection decision. At higher organizational levels, an increasing number of contextual and strategic factors can influence such decisions. The decision makers, typically CEOs and boards of directors, have little knowledge of personnel selection procedures and somewhat limited experience in making executive selection decisions. However, some research shows that leaving executive selection, especially executive succession programs, primarily in the hands of human resource professionals can result in less effectiveness. In his review, DeVries noted that instances of successful executive selection, senior line managers, CEOs, and directors tend to take a more holistic and contextual approach to selection decisions.

Some researchers such as Rob Silzer in 2002 have argued that executive selection decisions should reflect the strategic and organizational context of the position. Different strategic challenges will require different mixes of executive competencies. For example, strategic change and innovation will require executives who have strong visioning and change management skills. Alternatively, executives who have strong industry knowledge, financial acumen, and social capital are likely to be more suitable for strategies that emphasize

accruing the financial benefits of high organizational performance in a fairly stable environment.

The top management team (TMT) represents another contextual factor that influences executive decisions. The selected executive needs to display values and core beliefs that are similar to those of the CEO and other TMT members. Alternatively, executive selection decisions can rest on what talents and capabilities possessed by candidates are different from those in the existing TMT, thereby expanding the collective human capital at the top of the organization. The acceptance of new executives with ideas and strengths that differ from those of existing TMT members will depend, however, on the perception that they share the core values and long-term strategic goals of the TMT.

SUMMARY

Effective executive selection decisions are most likely to emerge from a process and system that adapts best practices in personnel selection to the recruitment, assessment, and selection of executive candidates. Yet these best practices must also be applied with serious consideration of the strategic, cultural, and social context of the organization as a whole. The recent surge in research on executive selection within industrial and organizational psychology provides significant promise for uncovering these best practices and understanding the contextual factors that drive their utility.

EXIT SURVEY (EXIT INTERVIEW)

Effective management of human capital provides a means for increasing productivity and reducing costs. The relationship between retention and profitability is clear—fewer turnovers translate to less expense for the organization. Leading organizations understand this fact and track employee attitudes and feedback across the entire employment life cycle (recruitment and on-boarding → integration → departure). These organizations strive to understand why individuals join, stay, and leave their company, so they can engage in superior human capital planning.

Although a great deal of research has been conducted on employee opinion and attitude surveys, relatively little focus has been devoted to exit surveys. This is somewhat surprising, given that the creation of a rigorous exit measure builds an organization's capability to understand why talent is leaving, what might have prevented them from leaving, and their attitudes toward the organization.

A number of considerations apply when creating or augmenting an existing exit survey process—namely, the target population, the content of the survey, the administration method, the likely response rate, and the reporting requirements.

POPULATION

Most exit surveys are sent only to employees who are voluntarily leaving the organization, the belief being that voluntary turns are considered regrettable losses. If an organization has limited resources to monitor or implement an exit survey, it might consider limiting the survey process to a select employee population

(e.g., employees identified as key talent). If your organization chooses to target (or omit) a particular group, you must be sure that the group can be clearly defined and that the survey is consistently administered to the population selected. Otherwise, the door is open to legal concerns around inconsistent or discriminatory treatment.

SURVEY CONTENT

In most cases, an exit survey is designed to gather information as to how the employee perceived his or her compensation, benefits, working conditions, opportunities for career advancement, workload, manager quality, and work–life balance, as well as the relationships between coworkers and supervisor.

An exit survey is typically a combination of multiple-choice, agree–disagree, and open-ended questions. There is great value in ensuring that any attitude or opinion questions included in the exit survey parallel those asked via internal surveys (see Table 1). In this way, the organization can compare responses obtained from stayers and leavers to gain an understanding of what truly differentiates them.

Ultimately, the content chosen for the survey should reflect the culture and values of the organization and provide information useful to enhance recruiting, retention, and employee engagement efforts. One cautionary note regarding open-ended questions: Former employees often have a great deal of feedback about the company, coworkers, management, and so forth. Unless your organization has the resources to regularly read, categorize, and address issues raised, it is recommended that only closed questions be used.

ADMINISTRATION METHOD

There are essentially three options for administering an exit survey: paper-and-pencil, Internet, and phone interviews. A paper-and-pencil survey is typically sent by mail 30 to 60 days after a person leaves the organization. The benefit of this process is that it is administratively efficient from the respondent's perspective—he or she completes the short survey and returns it via a stamped, addressed envelope. The major drawback is the administrative resources needed to create the mailing and capture the information once it is received. Scannable forms reduce the burden, but it is still an administratively cumbersome activity.

Table 1 Example Linkages Between Internal and Exit Survey Questions

<i>Internal Employee Survey Question</i>	<i>Corresponding Exit Survey Question</i>
I am compensated fairly (base salary, bonus).	I was compensated fairly (base salary, bonus).
I am confident I can achieve my career goals at ABC Company.	I could have achieved my career goals at ABC, if I had chosen to stay.
The amount of work I am expected to do is reasonable.	The amount of work I was expected to do was reasonable.

Table 2 Pros and Cons Associated With Different Administration Methods

<i>Administration Method</i>	<i>Pros</i>	<i>Cons</i>
Paper-and-pencil	Administratively efficient for the user	Administratively cumbersome for the organization
Internet	Automated gathering and processing of information	Administratively cumbersome for the user—access not readily available
Phone interview	Potential for greater engagement than with other methods and affords opportunity to address concerns	May be viewed as invasive, time-consuming, or expensive

Internet-based exit surveys offer the benefit of online data collection. The main drawback has to do with accessibility. As the employee is asked to complete the survey after leaving the organization, access to the Internet may not be readily available, and the former employer will typically not have a personal e-mail address for the employee. Anecdotally, our experience suggests that the benefits of a paper-and-pencil survey outweigh the administrative ease of an Internet-based survey. We have seen marked improvement in our response rates after moving from an Internet-based to a paper-based survey.

An interview approach to exit surveys should not be confused with an exit interview. (*Exit interview* typically refers to an interview that occurs with an employee before he or she departs the organization.) Although phone interviews are not as common as an Internet or paper-based survey, some organizations have chosen to administer their questions via telephone. The benefits are that the information gathering process is more engaging and that concerns can be addressed directly. The drawback is that a former employee might find the phone interview too invasive. Table 2 summarizes the benefits and drawbacks of each administration option.

In addition to identifying *how* the survey should be administered, you must also determine *who* should manage or administer the survey. Most organizations choose to have an outside vendor administer the survey and process the information. Typically, a vendor can manage the process more efficiently and at a lower cost than if the process was managed in-house. In addition to cost and efficiency benefits, a vendor can also serve as a middle person between the organization and the former employee. More specifically, the vendor can obtain candid or sensitive information from the former employee and feed it back to the organization after all identifying information has been removed.

RESPONSE RATES

As with any survey, you must design the survey and communications in such a way as to maximize responding. A low response rate will call into question the accuracy and generalizability of the survey findings and greatly limit the extent to which you can cut the data to provide insights at a business unit or function level. One recommendation is to keep the survey short; keep it to one page if possible. There is a difference between what you *want* to measure and what

you *need* to measure to meet your objectives—focus only on what you need to know.

You might also consider providing an incentive. For example, you could offer the chance to win a valued prize in a drawing for individuals who complete the survey. Using a vendor to manage the process allows for the individual to enter the drawing and still maintain the former employee's anonymity.

Another innovative technique that has been used is to appeal to the values of the individual. One organization offers a donation to a prominent charity for each exit survey that is returned. Thus, the respondent is helping the organization as well as helping a good cause.

REPORTING

When creating an exit survey process, it is important to clearly identify (a) what information needs to be reported; (b) how often the information needs to be reported; and (c) who will have access to the information. To maximize the usefulness of the survey, the information should be easily accessible to all key stakeholders. There are generally three options: (a) The vendor provides all reports; (b) a center of excellence within the company creates and distributes information; or (c) a reporting tool is created that allows key stakeholders to access information to meet their specific needs. Based on our experience, we recommend the third option. Exit survey information is most useful when it is being analyzed to address or provide clarity to a specific business issue—allowing access to the individuals who need it means the data can be used to inform decision making in a timely manner.

A well-created exit survey can be a powerful tool for gathering important information relative to reasons why valued employees are leaving the organization. Gathering this information is not without difficulties. Ensuring you have a meaningful response rate, are receiving candid responses, and are maintaining an efficient process while gathering actionable information to inform decision making are just a few of the challenges involved. Nonetheless, the time and investment are worth it if you truly hope to engage in superior human capital planning.

EXPATRIATES

Expatriates are employees who go overseas to accomplish a job-related goal. To remain competitive in the world marketplace or to obtain new marketing opportunities, multinational companies (MNCs) are sending increasing numbers of expatriates on international assignments. In fact, recent research estimates that more than 250,000 Americans currently are serving as expatriates on international assignments. This number is expected to continue to increase with further economic globalization.

There exist several characteristics shared by expatriates. Foremost, expatriates are expected to accomplish assignments in a different country or culture. This change typically introduces expatriates and their families to new living and working environments. A second characteristic of expatriates is that their international assignments are usually complex in nature. For example, many MNCs expect the expatriates to open a new market, transfer skills, and build good public relations with local organizations and medias. Because of the complexity of these assignments, most expatriates tend to be senior managers whose jobs involve a high degree of responsibility. In fact, expatriates' performances can directly affect the success of their respective MNCs' competitive standing in the global marketplace. A third characteristic of expatriates is that they are usually expected to complete their assignments in a predesignated time period (usually ranging from 6 months to 5 years). After this time period, expatriates are sent back to their home country

and assigned to a new position, a process termed *repatriation*.

BENEFITS FOR EXPATRIATES

To compensate for the disadvantages expatriates and their families may face while on international assignment, most MNCs' compensation policies are quite generous. The typical compensation package offered to expatriates includes one or more of the following: overseas premiums, cost-of-living allowances, housing allowances, children's education allowances, hardship allowances, car allowances, and home leave allowances. Further, performance-based bonuses, as well as seniority bonuses, are common, and exchange risk and taxation differences are usually taken into consideration. The total compensation package offered to expatriates could be equal to several times the salary package in the home country for the same position. This shows the considerable costs associated with expatriate assignments. Although the average onetime cost for relocating an expatriate overseas is \$60,000, supporting an expatriate working on an international assignment may cost more than \$220,000 annually.

Being well compensated is not the only benefit for expatriates. Gaining international experience can enhance one's career. Numerous researchers have noted that many successful expatriates are subsequently promoted during repatriation. Further, more and more MNCs are sending their high-potential candidates for senior leadership positions on international assignments as part of their career development. Success in the expatriate assignment often then becomes part of the selection process into higher-level positions. This process seems to be well understood by expatriates, and researchers have documented that expatriates expect to be promoted on successful completion of their assignments.

CRITERIA OF EXPATRIATE SUCCESS

An expatriate's job performance on international assignments and whether the expatriate returns to his or her home country before the assignment contract expires (i.e., premature return) are two criteria often used to evaluate expatriate success. These two criteria clearly reflect the fact that expatriate success means effective and timely completion of the international assignment.

Expatriate Job Performance

The multidimensionality of expatriate job performance is well accepted by researchers. A typical expatriate job performance model usually includes the following intercorrelated components:

- *Establishing and maintaining business contacts.* Identification, development, use and maintenance of business contacts to achieve international assignment goals
- *Technical performance.* Fulfillment of specific task requirements on the international assignment
- *Productivity.* Volume of work produced by the expatriate
- *Working with others.* Proficiency in working with others (i.e., local workers and other expatriates), assisting others in the organization
- *Communicating and persuading.* Oral and written proficiency in gathering and transmitting information; persuading others
- *Effort and initiative.* Dedication to one's job; amount of work expended in striving to do a good job
- *Personal discipline.* The extent to which counterproductive behaviors at work are avoided
- *Interpersonal relations.* The degree to which the expatriate facilitates team performance and supports others in the organization and unit
- *Management and supervision.* Proficiency in the coordination of different roles in the organization
- *Overall job performance.* Composite of all dimensions of expatriate job performance described in previous points

Expatriate Premature Return

Expatriates are typically expected to complete international assignments in a predesignated time period. Adhering to this time frame is usually critical for two reasons. First, the time frame likely involves critical timing of the introduction of new products or services in the global market. Second, as mentioned, tremendous annual costs accrue to the organization to support such employees. Therefore, expatriate premature return usually indicates failure on the international assignment, which results in high-accrued costs and potential risk concerning global competitiveness for the organization. For expatriates, premature return is more than simply changing or quitting a job—it is a relocation that brings them back to cultures and environments with which they are familiar. Compared with the 5% average domestic turnover rate, expatriate

premature return rates can be extremely high (e.g., from 16% to 40%).

PREDICTORS OF EXPATRIATE SUCCESS

There are two types of predictors that associate with expatriate success. One type, *proximal predictors* (i.e., international adjustment variables), directly relates to expatriate success. The other type, *distal predictors*, indirectly affects expatriate success through proximal predictors.

Proximal Predictors

Research on expatriates has identified three variables as proximal predictors of expatriate success: general adjustment, interaction adjustment, and work adjustment. *General adjustment* refers to expatriates' comfort associated with various nonwork factors such as general living conditions, local food, transportation, entertainment, facilities, and health care services in the host country. *Interaction adjustment* refers to expatriates' comfort associated with interacting with host country nationals, both inside and outside of work. *Work adjustment* refers to expatriates' comfort associated with the assignment job or tasks.

A wealth of data has supported direct relationships between these three international adjustment variables and both expatriate job performance and premature return. Expatriates with higher levels of these types of adjustment are more likely to have high levels of job performance and are less likely to return to the home country early.

Distal Predictors

Five categories of distal predictors of expatriate success have been identified by meta-analytical research. They are *anticipatory factors*, *individual factors*, *job factors*, *organizational factors*, and *non-work factors*.

Anticipatory factors are related to predeparture expatriate preparations for the upcoming assignment. These factors include the expatriate's language ability (fluency in the host country language) and previous overseas assignments (prior experience in living and working abroad). Expatriates with better language ability have higher levels of interaction adjustment and work adjustment. Expatriates with more previous

experience generally have higher levels of general adjustment and interaction adjustment.

Individual factors are personal requirements for effectiveness in the overseas environment. These factors include the expatriate's self-efficacy (i.e., beliefs in one's own ability to execute plans of action) and relational skills (i.e., skills that facilitate the formation of interpersonal ties). Higher self-efficacy is related to higher levels of interaction adjustment and work adjustment. Better relational skills are related to higher levels of all three kinds of international adjustment.

Job factors are features of the work environment over which the expatriate has little or no control. These factors include role clarity (i.e., exact understanding of position requirement), role discretion (i.e., decision-making autonomy), and role conflict (i.e., incompatible cues regarding job expectations). Research has supported relationships between all of these job factors and expatriates' work adjustment. Expatriates experience higher levels of work adjustment when the role clarity and role discretion are high, and they experience lower levels of work adjustment when the role conflict is high.

Organizational factors are features of the overseas or parent company's policies and culture. In an expatriate context, the most important organizational factors are coworker support (i.e., social support from coworkers) and logistical support (i.e., assistance from the parent company with respect to day-to-day aspects of living). Expatriates who experience higher coworker support have higher levels of work adjustment. Expatriates who experience higher logistical support have higher levels of general adjustment and interaction adjustment.

Nonwork factors are features of the expatriate context that are not in the job domain. These factors include family adjustment (i.e., how well one's family adapts to the overseas environment) and cultural novelty (i.e., the discrepancy between host and home cultures). Higher family adjustment has been found to lead to higher levels of all three kinds of international adjustment, whereas higher cultural novelty has been found to lead to lower levels of all three kinds of international adjustment.

SUMMARY

Because of economic globalization, the past two decades have seen a steady growth of expatriate research. Literature in this area supports two

conclusions: (a) Expatriate success is best evaluated via expatriate job performance and premature return; and (b) expatriate adjustment is of great functional importance in expatriate assignments.

EXPECTANCY THEORY OF WORK MOTIVATION

Among the most influential theories of work motivation to appear during the second half of the 20th century in Western psychology and organizational behavior was, in fact, a body of theories that were all variants of an expected-value formulation. In a

nutshell, these theories held in common the premise that the motivational force a person would feel toward a particular choice (or position or alternative) was a joint, multiplicative function of the individual's beliefs about the expected value of the outcomes that the choice alternative would bring about, multiplied by the perceived probability that the outcome would result from selecting that choice (or position, or alternative). These models assume that an individual would form beliefs and perceptions about all (or at least some) of the most salient alternatives available at any choice point and select to act in accordance with the alternative that yields the highest subjective expected utility, or payoff.

A few key elements of the model must be emphasized. (We have acknowledged that a variety of expectancy theory models are available. For ease of description, however, we will refer to them as a collectivity, in the singular case.) First, notice that expectancy theory is a *within-person decision-making model*: the individual chooses to behave in accordance with the alternative that she or he associates with the highest subjective expected utility. It was never intended to be predictive of differences *across* individuals in terms of the choices they make.

Second, note the perceptual nature of the major parameters of the model. It is referred to as *expectancy* theory for a good reason. The major parameters are all perceptual and based on the individual's beliefs. Naturally, in any case, the person's perceptions may be inaccurate or his beliefs may be false. The nature of these various beliefs and perceptions, accurate or otherwise, determines the motivational force toward any particular decision alternative.

Third, the elements of the model are combined in the mind of the individual multiplicatively. Therefore, if a given decision alternative has no positive outcomes associated with it in the mind of the person, this zero value will result in a nullification of the force associated with that decision alternative. The same would occur if the person sees no likely connection between selecting an alternative and the receipt of the outcome.

A PRELIMINARY WORKING EXAMPLE

So, for example, if Sally is considering job offers from two prospective employers (a large grocery store and a small florist), and having regular time off for travel is important to her, she will consider the expected value of time off (which should be constant for her as

she considers the two job offers) as well as the odds, in her mind, of receiving regular time off under either of the two employment relationships. If the florist tells Sally that it is important that their staff be available 7 days a week and on call when business increases sharply, she may believe that the likelihood of getting time away from the flower store is small. If, on the other hand, the union contract held by the employees at the large grocery store guarantees holidays and generous vacation periods for its members, Sally would perceive (assuming she had researched the comparative time-off provisions of the two organizations carefully) that her chances of getting time for travel would be higher if she were to accept the unionized grocery clerk position. By the formulation of the expectancy theory model, the vacation-oriented considerations would contribute positive motivational force toward selecting the grocery store.

But, of course, Sally would likely have many other things to consider in addition to her vacation desires. She may also be quite concerned about the comparative pay levels offered by the two stores, the proximity of the two jobs to her apartment, the physical demands placed on her by the two jobs, her chances to learn a trade or occupation, and also the nature of the supervision under which she would have to work. In the same way that Sally had perceptions and beliefs about the vacation issues related to the two alternatives, she would have beliefs about the expected value to her of the pay levels, proximity factor, physical demands, career possibilities, and supervisory conditions associated with the two jobs.

Perceptions about expected value of outcomes such as these are referred to as *valences* (e.g., the expected value associated with the chance to learn a trade may be very high for Sally; in the lexicon of the theory, it would be said that career advancement holds high valence for Sally). It is the expected value—valence—that matters in contributing to motivational force, not the real value. In this case, learning a trade may, in fact, not turn out to be of value for Sally, even though at the time she is facing her job dilemma she believes it to be important. In summary, Sally would consider the expected value (or valence) associated with a range of work-related outcomes as she considers the two job alternatives. Presumably, the valence associated with any one of these outcomes would be constant across the alternatives, although some versions of the theory allow for other parameters in the model to influence valence beliefs.

Sally would also form beliefs about the probable connection between accepting the job at the grocery store and receiving certain levels of these outcomes. So, for example, the hourly pay at the grocery store may be considerably higher than at the small, independent flower store. In such a case, the terms of the theory would say that accepting the job at the grocery would be *instrumental* for earning high pay, whereas taking the job at the florist would not be instrumental for high pay. Given that high pay holds high valence for Sally and that she believes (correctly or otherwise) that high pay would be associated with the grocery job but not with the flower job, the high instrumentality belief, multiplied subjectively in her mind by the high valence for pay, would make a potent motivational force in favor of electing to join the grocery clerks' union. But Sally would consider the odds of attaining the other outcomes, as well, were she to select either the florist or the grocer. The theory assumes that Sally will subjectively consider the valences of all the outcomes of interest to her, each multiplied subjectively by her subjective beliefs (or instrumentality beliefs) of attaining these outcomes at both the flower store and the grocery, and be more highly motivated to select the store that, in her mind, represents the higher aggregate of the products of her valence and instrumentality beliefs.

Notice that it is possible that a single consideration could trump the analysis. For example, if the grocery store job requires Sally to travel to work at one of its many outlets on 2 hours' notice on a given day, she may decide that it is not feasible for her to take the grocery clerk position, given that she does not own a car, public transportation is scarce, and the stores are widely dispersed across the large city in which she lives. Meanwhile, the florist, whose small shop is located a block from Sally's apartment, appears very attractive on the proximity dimension. According to the theory, the very high negative valence (i.e., expected negative value of travel time to work) may sweep the decision, swamping the subjective expected utility represented by the (valence \times instrumentality) beliefs contributed by the other factors in Sally's decision model (pay levels, time off for vacations, and so on).

REVIEW OF TERMINOLOGY

To summarize, *valence* is the expected value of an outcome associated in the mind of the individual with a choice alternative. The strength of this parameter

varies as a function of the person's values and needs and can be estimated on the basis of personal experience, vicarious experience, or simple hunch. Valences can range from highly positive (often calibrated as +1.0 in statistical tests of the model); through indifference, or no expected value (calibrated as 0.0 mathematically); to highly negative, or aversive (calibrated as -1.0). Again, the person's valence for an outcome may or may not be an accurate estimate of true value to him or her of that outcome, but it is the valence that matters.

Instrumentality is the subjective probability in the mind of the person that an act (such as selecting a job at a store, joining the army, marrying another person, or working hard on the job) will lead to a particular outcome. Different approaches calibrate expectancies different ways. Preferable approaches are those in which expectancy is conceived of as ranging from 0.0 (which implies that there is no expectation in the mind of the individual that an act will result in a particular outcome—for example, Sally may legitimately see no likely connection between working for the florist and being able to travel on the spur of the moment), to 1.0, which implies that the person sees a 100% chance that an act will result in an outcome. In our example, Sally would be wise to see such high expectancies for crosstown travel on foot and by bus, as well as membership in the clerks' union, if she were to accept the job at the grocery chain.

Some versions of the theory explicitly add a component referred to as *expectancy*. In these versions, expectancy is the perceived probability (again, in the mind of the decision maker) that making any particular choice is possible. Here is an example: If Henry is trying to decide whether to pursue a grade of A in his math class, he may have subjective beliefs about whether attaining an A is possible, given his low aptitude for calculus and geometry. He may believe that even if he worked day and night, his mind is just not made for mathematical concepts, so there is no sense in trying for an A and wasting time and effort that could be used to gain good grades in other courses. If Henry firmly believes that an A in math is not possible (i.e., in his mind, the probability that effort would result in an A is 0.0), Henry would not bother to try for the A. Sally, the math whiz who knows she can get an A, would have an expectancy estimate of 1.0. So she would likely pursue that high mark. In these models, the expectancy factor (which ranges from 0.0 to 1.0) is conceptually multiplied by the aggregate of the

products that resulted in Henry's mind from the positive and negative outcomes of earning an A, each multiplied by the probabilities that the A would, in fact, get him those outcomes (such as Sally's admiration, a chance for a scholarship, etc.).

MULTIPLICITIES OF OUTCOMES

To this point, we have discussed extrinsic outcomes in the decision models of our examples, Sally and Henry. *Valence-instrumentality-expectancy* theories (which is the preferred term here) make room for the inclusion of intrinsic outcomes such as feelings of achievement, self-esteem, and self-actualization. They also include negative outcomes, as we saw in the case of Sally, who considered the crosstown travel for the grocery chain as aversive.

SUCCESSSES AND FAILURES OF THE THEORY

Valence-instrumentality-expectancy (VIE) models have enjoyed considerable success in the prediction of many within-individual choice situations in a variety of disciplinary and problems areas, such as work motivation (how hard to work, which position to accept, whether to retire, etc.), marketing (which brand of product to buy), and many others. Researchers have made many errors over the years in testing VIE models, however. Some have attempted to measure a model's components with invalid scales. Others have attempted to use criterion variables other than individual choices among within-person alternatives, preferring instead to attempt to correlate predicted VIE composite scores with between-persons measures of criterion variables. Often the criterion variable has been a between-person measure of performance rather than effort, preference, or motivational force (the latter three being what the theory claims to be able to predict). Indeed, probably the most common "test" of VIE theories has been to validate hypothesized variances in individual work effort (even though performance has been used to operationalize effort).

CRITICISMS, VARIATIONS, AND ASSESSED VALUE

Many have criticized VIE models on the grounds of the requirements they assume for human rationality. These critics argue that no person is as rational as

these models assume, taking into account multiple outcomes at each decision point and making judgments about the valences and expectancies and instrumentalities associated with each outcome. Some point out that habits and impulses frequently trump rational behavior, making valence, instrumentality, and expectancy perceptions and beliefs irrelevant.

Notwithstanding the validity of the criticisms of the inherent assumptions made by VIE models, and despite the mixed record of empirical support the theory has produced in more than 40 years, VIE models have proven robust and highly useful in many theoretical and applied settings, particularly when tested using valid measures and operationalized as within-person decision models rather than between-persons models, using appropriate criterion measures. Moreover, VIE models have given birth to many variations that have included learning loops and insights into the processes through which estimates of the major parameters are formed and modified over time and with experience by individuals. But interest in VIE models has flagged in recent years, in large measure because they seem to have demonstrated their value and because two generations of critics, scholars, and researchers have exhausted the possibilities for new refinements, new applications, and fresh criticisms. Nevertheless, and on balance, these models are highly regarded and are expected to continue as members in good standing of the family of useful theories of work motivation.

EXPERIMENTAL DESIGNS

The validity of inferences stemming from empirical research in industrial and organizational psychology and allied disciplines is a function of a number of factors, including research design. *Research design* has to do with the plan, structure, or blueprint for a study. The literature indicates that among the components of such a plan are (a) the experimental design type (i.e., randomized experiment, quasi-experiment, and non-experiment); (b) the study setting (e.g., created for the purpose of doing research); (c) the numbers and types of study participants; (d) the way in which the variables considered by the study are operationally defined; and (e) the techniques that will be used to analyze the data produced by the study. The focus here is on the randomized experiment. It differs in important ways from both nonexperimental and quasi-experimental design types.

Prior to considering the nature of randomized experiments, we consider several issues concerning the validity of inferences stemming from empirical research. Note that the same issues apply not only to randomized experiments but also to quasi-experiments and nonexperiments.

FACTORS AFFECTING THE VALIDITY OF RESEARCH-BASED INFERENCES

The overall correctness of inferences (e.g., research-based conclusions, recommendations for practice) stemming from a study is a function of its design and the manner in which it is actually conducted. Four facets of validity are critical: construct validity, statistical conclusion validity, internal validity, and external validity, as noted by Thomas Cook and Donald Campbell in 1979, and by W. R. Shadish, Cook, and Campbell in 2002.

Construct Validity

Construct validity is a function of the degree of correspondence between the constructs dealt with by a study and their realizations. It has to do with not only the operational definitions of variables (e.g., manipulations, measures), but also the empirical realizations of other features of a study (e.g., types of participants, research settings). Construct validity

inferences are threatened by a number of factors, including inadequate preoperational definitions of constructs, study procedures that lead participants to guess a study's hypotheses and behave in ways that confirm them, operational definitions that underrepresent focal constructs, and a lack of correspondence between the type of participants in a study and the way the participants are labeled by a researcher.

Statistical Conclusion Validity

Statistical conclusion validity has to do with the correctness of inferences about relations between variables that stem from the results of statistical tests. Among the factors that threaten this facet of validity are testing statistical hypotheses with data that violate relevant assumptions (e.g., homogeneity of variance), implementing treatments unreliably within study conditions, conducting research in settings having random irrelevancies (e.g., fluctuations in noise, temperature, illumination), and sampling too few units (e.g., participants) to provide for adequate statistical power in hypothesis testing.

Internal Validity

Internal validity is the degree to which inferences about causal connections between variables are correct. Among the factors that detract from the validity of such inferences are history, maturation, instrumentation, testing, selection, and mortality.

External Validity

External validity deals with the correctness of inferences about the generalizability of a study's findings to and across populations of settings, participants, time periods, and so forth. External validity is threatened by such factors as interactions between settings and treatments, interactions between history and treatments, and interactions between selection and treatments.

DEFINING ATTRIBUTES OF RANDOMIZED EXPERIMENTS

Randomized experiments have four major characteristics. Taken together, these serve to differentiate randomized experiments from both quasi-experiments and nonexperiments.

Manipulation of Variables

In randomized experiments, the researcher manipulates (as opposed to measures) the values of the study's independent variables (e.g., X_1, X_2, \dots, X_j). In theory, there is no limit on either (a) the number of variables that might be manipulated in any given study or (b) the number of levels of each of the manipulated variables. In practice, however, experiments have relatively small numbers of *conditions*—that is, unique combinations of independent variables and levels of such variables. One reason for this limitation is that the greater the number of conditions, the more difficult it is to conduct the experiment. Another reason is that statistical power considerations militate against experiments having large numbers of conditions. Yet another reason is that the theories or models that guide research often consider only a limited set of the assumed causes of a study's dependent variables. Nevertheless, a requirement of a randomized experiment is that there must be at least two levels of one (or more) independent variable(s). However, contrary to what many appear to believe, there is no requirement that there be any control group, including a nontreatment control group. For example, a study dealing with the effects of variations in job design on job satisfaction could contrast relatively low and high worker autonomy conditions. There would be no need for an autonomy control condition. However, the manipulated levels of worker autonomy would have to differ enough to produce changes in measured levels of the study's dependent variable (i.e., job satisfaction).

Randomized experiments are often of the factorial variety. In factorial experiments, there are two or more independent variables and each such variable has at least two levels. For example, the just described job design study could be modified to make it factorial by adding a second independent variable, such as task variety. A major advantage of a factorial study is that it allows for testing both the main and interactive effects of independent variables on a study's dependent variable(s).

One of the important reasons for manipulating the levels of independent variables is that doing so ensures that assumed causes occur before assumed effects. This temporal precedence is vital to the internal validity of research.

Random Assignment of Units to Conditions

In randomized experiments, research units (e.g., individuals, groups) are randomly assigned to conditions. This randomness is critical because it serves to greatly enhance internal validity. The major reason for this enhancement is that when a sufficiently large number of units have been randomly assigned to study conditions, these conditions will be highly alike with respect to any and all variables prior to the time independent variables are manipulated. As a consequence, the posttreatment levels of dependent variables across conditions will be a function of the study's manipulations, as opposed to initial differences in such variables across the same conditions.

Measurement of Dependent Variables

The effects of the study's manipulations are assessed through measures of dependent variables. In the case of research involving human participants, the measures can focus on such outcomes as attitudes, beliefs, intentions, psychological states, and behaviors. Among the types of measures that might be used are observations of behaviors, questionnaires, ability tests, and physiological measures.

In many experiments it is valuable to assess the degree to which the manipulations have had desired effects on study participants. Such assessments use measures known as *manipulation checks*. For example, in the job design study described previously, a researcher could use questionnaires to assess differences in participants' beliefs about the amount of discretion they had over the way the job was performed in the relatively low and high autonomy conditions. Manipulation checks are important in interpreting the results of a study, especially when its manipulations fail to produce expected changes in the values of dependent variables. In such cases, manipulation check data can be used for internal analyses, as noted by Elliot Aronson, Phoebe C. Ellsworth, J. Merrill Carlsmith, and Marti H. Gonzales in 1990.

Control Over Extraneous or Confounding Variables

Randomized experiments that are well designed and properly conducted provide for high levels of control over any and all factors that might influence the

values of dependent variables other than the manipulations. There are several strategies for achieving such control. One is to make experimental conditions equivalent to one another in terms of all factors other than the manipulations to which participants are exposed. Another is to ensure that in the course of participating in the experiment, participants are not differentially exposed to extraneous influences (e.g., environmental events).

RESEARCH SETTINGS VERSUS EXPERIMENTAL DESIGN TYPES

It is important to recognize the distinction between experimental design types and research settings. Design types include randomized experiments, quasi-experiments, and nonexperiments. All of these can be used in a variety of settings. Typically, research settings have been characterized as being of either the laboratory or field variety. However, the distinction between the laboratory and the field is not always clear, as observed by, among others, J. P. Campbell in 1986 and E. F. Stone-Romero in 2002. Thus, a better distinction involves a contrast between settings that are either (a) created for the specific purpose of doing research (special purpose setting) or (b) created for purposes other than research (non-special purpose setting). In general, special purpose settings exist for relatively short time periods, and they cease to exist when the study for which they were created has been completed. In addition, they are designed to ensure that independent variables can be manipulated effectively. As such, the literature indicates that they may have fewer features or elements than would be found in non-special purpose settings. Nevertheless, Elliot Aronson and colleagues wrote in 1990 that it is (a) vital that settings have *experimental realism* and (b) desirable that they have some degree of *mundane realism*. For example, a researcher interested in studying the effects of variations in task characteristics on task satisfaction could create a special purpose setting in either a university laboratory or a nonuniversity facility (e.g., a building in an industrial park). For such a study, it would be important to have tasks that were meaningful enough to have desired degrees of impact on research participants, thus ensuring experimental realism. However, it would not be important to have other elements that would be found in an actual organization (e.g., incentive systems, fringe benefits). Nevertheless, the greater the extent to which such

elements were part of the study's setting, the greater would be the mundane realism of the study.

The previously described task characteristics of a study also could be conducted in a non-special purpose setting (e.g., an actual work organization). However, it would typically be much more difficult to conduct the study in such a setting. One reason for this difficulty is that in most such settings it is very difficult to effect the changes in existing organizational arrangements (e.g., physical layout of facilities, assignment of workers to jobs, pay and fringe benefits provided workers). Thus, experiments in non-special purpose settings typically have lower levels of control over extraneous or confounding variables than do experiments performed in special purpose settings, and internal validity is more suspect in settings of the former than the latter variety. However, studies in non-special purpose settings typically have higher levels of mundane realism. Often, this serves to bolster their external validity.

EXPLORATORY FACTOR ANALYSIS

See FACTOR ANALYSIS

F

FACTOR ANALYSIS

Factor analysis is a statistical procedure for describing the interrelationships among a number of observed variables. Factor analysis is used to measure variables that cannot be measured directly, to summarize large amounts of data, and to develop and test theories. There are two broad categories of factor analysis: exploratory and confirmatory. Exploratory factor analysis techniques have a much longer history than confirmatory factor analysis techniques. Differences in the approaches lead to different uses (e.g., theory development versus theory confirmation).

PURPOSES

Factor analysis has three fundamental purposes. First, it is useful for measuring constructs that cannot readily be observed in nature. For example, we cannot hear, see, smell, taste, or touch intelligence, but it can be inferred from the assessment of observable variables such as performance on specific ability tests. Factor analysis is also helpful in the development of scales to measure attitudes or other such latent constructs by assessing responses to specific questions. Second, factor analysis is useful for summarizing a large amount of observations into a smaller number of factors. For example, there exist thousands of personality descriptors in the English language. Through factor analysis, researchers have been able to reduce the number of distinct factors needed to describe the structure of personality. Third, factor analysis is useful for providing evidence of construct validity (e.g., factorial, convergent, and discriminant validity). For

example, if certain observable variables are theoretically related to one another, then factor analysis should demonstrate these theoretical relationships, simultaneously demonstrating that the same variables are reasonably uncorrelated with variables from other latent factors. All three of these uses of factor analysis can be employed in the development and testing of psychological theories.

BASIC FACTOR MODEL

The basic factor analysis problem takes a number of observable variables and explains their interrelationships in a manner that is analogous to a regression equation. The common factor model is a regression equation in which the common factors act as predictors of the observed X variables. The basic factor model is depicted in Equation 1.

$$X = Lf + u \quad (1)$$

In this equation, X is the matrix of observed variables, L is the matrix of factor loadings or regression weights, f is the matrix of common factors, and u is the matrix of residuals. The goal is to explain the interrelationships among the X variables by the common factors, f , and the residual error terms, called *uniqueness*. The variance in X is partitioned into common and specific components. Unlike regression, however, the predictors, f , are unknown.

To provide a fictional example of this problem, suppose a number of supervisors are asked to rate the relevance of six personality characteristics to effective job performance by subordinates. The characteristics assessed are *organized*, *systematic*, *careless*, *creative*,

Table 1 Hypothetical Correlation Matrix of Observed Variables

Variable	1	2	3	4	5	6
1. Organized	1.00					
2. Systematic	.72	1.00				
3. Careless	-.63	-.55	1.00			
4. Creative	.00	.00	.00	1.00		
5. Intellectual	.00	.00	.00	.56	1.00	
6. Imaginative	.00	.00	.00	.48	.42	1.00

NOTE: These are hypothetical correlations based on imaginary supervisory ratings of "how important are these characteristics in an employee."

Table 2 Factor Pattern Matrix With Communalities and Uniqueness for Hypothetical Data

Observed Variable	Factor 1 Conscientiousness	Factor 2 Intellect	Communality (h^2)	Uniqueness ($1 - h^2$)
1. Organized	.90	.00	.81	.19
2. Systematic	.80	.00	.64	.36
3. Careless	-.70	.00	.49	.51
4. Creative	.00	.80	.64	.36
5. Intellectual	.00	.70	.49	.51
6. Imaginative	.00	.60	.36	.64
Sum of squared loadings	1.94	1.49		
Proportion of variance	$1.94/6 = .32$	$1.49/6 = .25$	$.32 + .25 = .57$	$1 - .57 = .43$

NOTE: Variance in each observed variable is 1; therefore, coefficients can be interpreted as standardized (i.e., in z-score form). Data are fictional for illustrative purposes only.

intellectual, and *imaginative*. Table 1 depicts the hypothetical correlation matrix for these variables. The factor analysis problem is to explain the relationships among these variables with fewer than six underlying latent factors. *Organized*, *systematic*, and *careless* are all correlated with one another, but they are not correlated with *creative*, *intellectual*, and *imaginative*. Likewise, *creative*, *intellectual*, and *imaginative* are all correlated with one another, but they are not correlated with *organized*, *systematic*, and *careless*. There are two sets of correlations reflecting two underlying factors.

Table 2 depicts the factor pattern matrix for these variables and the corresponding latent factors. The pattern coefficients in Table 2 (columns 2 and 3) are the correlations of the observed variables with the factors. Different pattern or loading matrixes will present different types of correlations (e.g., Pearson correlations, partial correlations).

The communality (h^2) in column 4 of Table 2 represents the variance that the variable has in common

with the factors it represents. The communality is analogous to a squared multiple correlation in regression. The uniqueness in column 5 represents the variance specific to a variable and not accounted for by the factor. Uniqueness is analogous to the residual variance in the observed variable after accounting for the factors. The six fictitious variables represent two unobservable factors, each factor accounting for 36% to 81% of the variance in the observed variables.

In addition to the variance associated with the observed variables, the factor analysis solution describes the variance in the factors themselves. The sum of the squared loadings (SSL) for a set of variables describes each factor's variance. Before any transformation in the factor loadings has taken place, these SSLs are called *eigenvalues*. Ideally, a small number of factors will account for a large amount of the variance in the observed variables. Table 2 shows that the factors account for 32% and 25%, for a total of 57% of the variance in the observed variables. The remaining

43% of the variance in the observed variables is not common to the factors.

EXPLORATORY FACTOR ANALYSIS

Typically, the goal of exploratory factor analysis (EFA) is to let the data determine the interrelationships among a set of variables. Although a researcher using EFA may have a theory relating the variables to one another, there are relatively few restrictions on the basic factor model in an EFA. This type of analysis has been useful in theory development and debate for more than a century.

Exploratory factor analysis is particularly appropriate in the early stages of theory development and in the early stages of scale or test development. First, EFA is useful in data reduction when interrelationships among variables are not specified beforehand. A researcher using EFA makes use of inductive reasoning by taking a number of observations and developing theory from those observations. In the example of high-performing employee characteristics, six personality variables were ultimately reduced to two factors. For subsequent analyses, then, only two variables need be discussed rather than the six original variables. Data reduction is particularly useful in alleviating the concerns of multicollinearity (correlations that are too high) among a set of predictors. A second benefit of EFA is the ability to detect a general factor. When several specific cognitive ability tests are factor analyzed, one general factor tends to emerge, along with several specific factors. In the assessment of intelligence, for example, all ability tests correlate to some extent with the general factor of intelligence, or *g*.

Finally, EFA is particularly useful in scale or test development because it allows the researcher to determine the dimensionality of the test and detect cross-loadings (correlations of variables with more than one factor). Cross-loadings are generally not desirable. In scale development, it is advantageous to have items that relate to only one factor. For the previous example, the three variables representing *conscientiousness* do not cross-load onto *intellect* and vice versa.

CONFIRMATORY FACTOR ANALYSIS

The goal of confirmatory factor analysis (CFA) is to test theoretically derived hypotheses given a set of data. The basic factor model of Equation 1 is still relevant, but certain restrictions are imposed given the

particular theoretical model being tested. For example, from the previous example, one could use CFA to impose restrictions on the factor pattern so that no cross-loadings are permitted. Developed during the 1960s, CFA is a newer statistical development than EFA (developed in 1904).

Confirmatory factor analysis is particularly useful in a deductive reasoning process. Specific hypothesis testing is possible when using CFA. For example, a researcher may address the statistical significance of individual factor loadings. In the previous example, given the relatively small correlation, one could determine with statistical certainty the degree to which the observed variable, *imaginative*, is correlated with the latent factor, *intellect*.

With CFA, it is possible to test the hypothesis that two factors versus only one factor (or any other numeric combination) underlie a set of data. In EFA, researchers rely on rules of thumb and intuition, which can lead the researcher astray, but in CFA, models can be explicitly compared through null hypothesis statistical testing. Another use of CFA is to assess the equivalence of parts of the basic factor model within a given data set. For example, one might hypothesize that all of the observed variables for *intellect* are equally related to *intellect*. With CFA, the equivalence of these relationships can be tested by imposing constraints on the loadings in the basic factor model (i.e., *L* in Equation 1).

It is also important to determine whether the results of a factor analysis are similar across demographic groups. Confirmatory factor analysis permits tests of invariance—that is, the equivalence of factor structure, loadings, uniqueness—across different groups (e.g., ethnic, gender, cultural) of individuals. A researcher may be interested in knowing whether the same hypothetical factor structure would emerge if responses from supervisors of manufacturing workers were compared with responses from supervisors of service workers. It may be the case that the observed variable do not relate to the latent factors in the same manner for the two groups. For example, the observed indicator *systematic* may be less related to the factor *conscientiousness* for service workers than for manufacturing workers. In a CFA that is testing for equivalence of factor loadings, a researcher can test the hypothesis that the correlations from the two groups are the same or different.

Confirmatory factor analysis has greater flexibility in control than EFA. With CFA, some factors may be

specified as *oblique* (correlated with one another), whereas others are specified to be *orthogonal* (uncorrelated with one another). Within a single EFA, the factors are interpreted as either oblique or orthogonal but not a combination of the two. In addition, CFA allows the researcher to flexibly impose additional constraints subject to theory (e.g., allowing correlated uniqueness). However, a benefit of EFA is that no such theoretical constraints or specifications are needed. Therefore, if none exist, then EFA may be a better choice.

FAMILY AND MEDICAL LEAVE ACT

The Family and Medical Leave Act (FMLA), which is intended to balance the demands of the workplace with the needs of families, became effective for most employers in August 1993. The passage of the FMLA

represented a legislative reaction to dramatic changes in the U.S. workforce that had taken place over the previous 40 years. During that period, the number of female workers in the civilian labor force increased by more than 200%. In addition, the American population is aging, leading some analysts to predict that an increasing percentage of workers will have some caregiving responsibility for an older family member. The number of single-parent households has also increased substantially as a result of increases in the number of unwed mothers and higher rates of separation and divorce. At the time of its passage, between 40% and 50% of the nation's workforce was estimated to be covered by the FMLA.

COVERAGE

Private-sector employers are covered by the FMLA if they are engaged in an industry or activity affecting commerce *and* if they employ 50 or more employees at a single work site or 50 or more employees at a group of work sites within a 75-mile radius for each working day during 20 weeks of the preceding or current calendar year. Contractual bargaining agreements that have arbitration clauses do not preempt claims under the FMLA. Public agencies—that is, federal and state governments, political subdivisions of the states, and private secondary and elementary schools—also are covered without regard to the number of employees.

LEAVE ELIGIBILITY

The major provision of the FMLA is that an *eligible employee* may take up to 12 weeks of unpaid leave during a 12-month period, to be used for specifically designated medical or family-related reasons. An eligible employee is an individual who has been employed for at least 12 months and has worked at least 1,250 hours during the previous 12-month period. If a husband and wife work for the same employer, only a total of 12 weeks of leave may be taken between them.

The circumstances under which the requested leave must be granted include (a) the birth of a newborn child, (b) the placement of a child with the employee for adoption or foster care, (c) the employee's own serious health condition, or (d) the serious health condition of a member of the employee's immediate family (spouse, son, daughter, or parent). The employer may require the employee—or the employee may

elect—to substitute family leave, vacation leave, or accrued paid personal leave for part of the 12-week period. Continuation of health insurance coverage must be provided by the employer during the period of leave, and the employee is entitled to restoration of his or her original position or an equivalent position after returning from leave. Having one's job restored after returning from leave is the predominant claim filed and litigated under the FMLA.

SERIOUS HEALTH CONDITION

A *serious health condition* is defined as an illness, injury, impairment, or physical or mental condition requiring inpatient care or continuing treatment by a health care provider, as well as any period of incapacity resulting from prenatal care or pregnancy. Whether a condition qualifies as a “serious” health condition is frequently litigated, and the determination is fact intensive; generalizations, therefore, are extremely speculative. For example, if the presentation is sufficiently severe, upset stomach (ulcer) or carpal tunnel syndrome may qualify as a serious health condition. On the other hand, an employee's heart arrhythmia or high blood pressure may not qualify as a serious health condition if the employee's doctor clears the employee for work and medical treatment can be obtained without missing work.

In one case, the termination of an employee who had been absent from work for four days to care for a child with an ear infection was not found to be in violation of the FMLA because the child's illness was not considered a serious health condition. In contrast, in another case, a teacher's mother who had fallen, leaving her incapacitated and unable to care for her own basic needs for several days (a condition compounded by other chronic health conditions), was considered to have suffered a serious health condition. Cosmetic or voluntary treatments that are not medically necessary may qualify if they require inpatient hospital care. Several diagnoses, none of which alone is a serious health condition but which are temporally linked, may rise to the level of a serious health condition when taken together.

The employer may require that the employee support a request for leave with certification from the health care provider of the employee, spouse, child, or parent on whose behalf leave is being requested. The employer also may require an opinion from a second provider, at the employer's expense. Conflicting opinions may be resolved—again, at the employer's

expense—by the opinion of a third health care provider, jointly approved by the employee and employer. The employer may request recertification under limited circumstances.

TIMING OF REQUESTED LEAVE

Under some circumstances, leave may be taken intermittently, in separate blocks of time from one hour to several days for medical appointments or treatment. Leave may also be taken on a reduced leave schedule, that is, a reduction in the number of working hours in a workday or workweek—for example, from full-time to part-time—if the employee and the employer agree. If intermittent leave or a reduced leave schedule is requested by the employee because of his or her own health condition or that of a family member, the employer may require the temporary transfer of the employee to an alternative position with equivalent benefits and pay. This option is available only if the need for intermittent leave is foreseeable. The employee is required give the employer 30 days or more notice before the requested leave is to begin, if the need for the leave is known ahead of time. The employee is not required to ask specifically for FMLA benefits. If the employer has notice that the employee might qualify, the employer has a duty to inform the employee that FMLA coverage might apply. Implementing regulations require the employer to provide information on FMLA rights and responsibilities to the employee, either in an employee handbook (if one is provided) or other written guidance.

ENFORCEMENT

For federal employees, the FMLA is enforced by the Office of Personnel Management. For private employers, the FMLA is enforced by the Wage and Hour Division of the U.S. Department of Labor. The administrative complaint procedure established by the Labor Department is not mandatory. Either the Labor Department or private individuals may bring an action in federal court for alleged FMLA violations. Generally, remedies are limited to lost wages (which may be doubled if it is found the employer did not act in good faith) and equitable relief, such as reinstatement or promotion. In a 2003 decision, the U.S. Supreme Court held that state government sovereign immunity provided by the Eleventh Amendment had been properly abrogated by Congress when the FMLA was enacted. The Court

held that a history of gender-based discrimination was sufficient to survive a heightened standard of review. As a result, public employers may now be sued by employees for monetary damages, as well as for equitable or injunctive relief.

OVERLAP WITH THE AMERICANS WITH DISABILITIES ACT

In some respects, the FMLA expands the rights provided under the Americans With Disabilities Act (ADA). Leave for medical conditions may be given as a reasonable accommodation under the ADA, although such accommodation is limited in several ways. First, under the ADA, an employee must be able to perform the “essential functions of the job” in order to be entitled to leave as a reasonable accommodation; this is not a requirement under the FMLA. Second, under the ADA, an individual must be disabled within the meaning of the statute; the Supreme Court has addressed the question of what qualifies as a disability. On the other hand, under the FMLA, the employee need only show the presence of a serious health condition, a less onerous burden. The Supreme Court has not yet had occasion to interpret the FMLA definition of serious health condition. Third, under the ADA, an employer may assert undue hardship in denying a requested accommodation and is not obligated to provide the employee with his or her preferred accommodation. Finally, if the employee qualifies for a reasonable accommodation of leave under the ADA, the time limitations of the FMLA may not apply, even though the leave is designated as FMLA leave. Problems arise for the employer when the employee does not specifically designate a request for leave as FMLA leave or as an accommodation under the ADA. Under such conditions, the employer must review all requests for leave under both the FMLA and the ADA.

FEEDBACK

Feedback is information that individuals receive regarding their performance and consists of a message that a sender conveys to a recipient. Feedback can motivate and guide effective behaviors as well as prevent ineffective behaviors. Thus, feedback can lead to positive behavior change and enhanced performance, and it can boost self-awareness and self-confidence. However, the ability of feedback to accomplish these goals depends on several factors. Employees vary in their receptivity to feedback, and this is influenced by characteristics of the source of the feedback, the nature of the message, and characteristics of the feedback recipient. In fact, some types of feedback can lead to negative reactions, such as job dissatisfaction, anger, or decreased effort. Factors that can improve the effectiveness of feedback are discussed here.

FEEDBACK DELIVERY

Feedback can come from a variety of sources, including supervisors, peers, direct reports, and clients. Employees are most receptive to feedback from sources who have high credibility. Sources are viewed as more credible when they are trustworthy and reliable. Moreover, feedback providers who have expertise related to the feedback will be perceived as more credible. In other words, even though the message may be valid, if it is not delivered by a credible source, the recipient may discount the feedback.

There are a number of ways to create a more effective feedback message. For example, feedback is most effective when it is specific and delivered on an ongoing basis. Avraham Kluger and Angelo DeNisi’s *feedback intervention theory* emphasizes that it is crucial to provide the correct level of feedback because feedback directs attention to how well an individual is meeting a particular goal. For example, feedback can be given at the self level, which then directs attention to the self (e.g., self-esteem). This type of feedback should generally be avoided because it may detract cognitive resources from the focal task. Feedback can also be task-focused, meaning that attention is focused

on the gap between current performance and a performance standard. Finally, feedback can be given at the task-learning level. This level involves the specific behaviors and actions that are necessary to perform the task. Kluger and DeNisi recommend that feedback be provided at the task level, but such feedback must include adequate information about how performance can be enhanced. Effective feedback should focus on controllable factors and include specific examples. Feedback is more effective when it is focused on the future rather than a rumination of the past. Furthermore, people are more likely to pay attention to feedback about an event that is unfamiliar, uncertain, and important.

Another characteristic of the feedback message that influences an employee's receptivity is the sign (either positive or negative) of the feedback. In general, positive feedback is more accurate and more accepted than negative feedback. Negative feedback may be viewed as less accurate and useful and may generate an emotional reaction. However, research has not consistently shown that negative feedback is ineffective. An important meta-analysis by Kluger and DeNisi found that feedback effectiveness does not depend on whether the feedback is positive or negative. Thus, it is important to consider this issue when giving feedback. Furthermore, employees who receive negative feedback may need different follow-up activities.

On the other hand, research has shown that the feedback recipient's expectations about the feedback play an important role in determining his or her reaction. For example, the discrepancy between self-ratings of performance and supervisor performance ratings may influence reactions above and beyond the feedback's sign. Moreover, a series of cognitive reactions occur after receiving feedback, such as perceptions of the feedback's accuracy or value. Feedback providers can control the way feedback is presented and should take the necessary steps to enhance its perceived accuracy. This research suggests that an individual's reaction to feedback is not overwhelmingly driven by the feedback's sign and that other factors also play an important role. Furthermore, negative feedback that is perceived as constructive and helpful for improving performance is often very well received.

FEEDBACK REACTIONS

Individual differences may affect an employee's receptivity to feedback and whether the feedback will

be used to improve performance. For example, employees who are focused on learning how to improve their performance (i.e., learning goal orientation) are more welcoming and receptive to negative feedback than are individuals who are focused on appearing competent (i.e., performance goal orientation). In addition, individuals who are high in conscientiousness and self-efficacy are more motivated to use feedback, whereas those who are high in anxiety and external locus of control may be less motivated to use feedback. Moreover, employees who are flexible, conscientious, agreeable, and emotionally stable tend to respond positively to feedback.

Because individuals may have negative reactions to feedback, feedback providers must be prepared to deal with recipients' defensive reactions, especially to negative feedback. Feedback providers should understand that change may unfold slowly as feedback recipients move through the stages of change. For example, the individual must first be aware that change is needed. Thus, feedback is important because it tells the employee that he or she is not meeting a particular standard. Second, the individual must prepare for change and work on a development plan with the supervisor. Next, the employee needs to take action to make the change. This may involve developmental activities such as specific job assignments or customized training. Finally, the individual must sustain the change. It is important for the feedback provider to understand the stages of change because each stage may require a different type of intervention.

Contextual factors such as the feedback culture or feedback environment of the organization also influence the way feedback is received. A positive feedback environment, which includes source availability, promotion of feedback seeking, and feedback quality, can affect the way an employee receives, processes, and uses feedback. The feedback environment can also influence employees' affective commitment, job performance, organizational citizenship behavior, and perceptions of politics.

A developmental intervention called *360-degree feedback* is often used to coach employees or to identify strengths to build on and weaknesses to improve. This tool is a mechanism for providing employees with feedback from a variety of sources, such as supervisors, subordinates, coworkers, and customers. Some evidence suggests that it can increase perceptions of others' competence and decrease perceptions of development needs. This tool should provide an

opportunity to include open-ended comments and other qualitative feedback, and it should center on competencies for development.

FEEDBACK SEEKING

In 1983, S. J. Ashford and L. L. Cummings challenged our traditional understanding of feedback in organizations. Until that time, feedback had been viewed primarily as a managerial resource that could be used to direct the behavior of employees toward desired goals. However, Ashford and Cummings's research shifted the focus of feedback from the giver to the receiver, describing feedback as a resource that can be elicited by employees when they experience uncertainty about how well they are performing. Since the publication of this seminal work, the idea that employees have some degree of control over the feedback they receive has become recognized and widely accepted. Feedback is no longer seen only as an organizational tool that can be used by a supervisor but as a resource that can be *managed* by any member of an organization, such as an employee. Feedback seeking occurs when employees purposefully monitor their work environment for performance information or ask others (such as supervisors or coworkers) for information about their performance.

FEEDBACK-SEEKING STRATEGIES

The basic human need to know how well one is performing is well-documented, and it is the basis for research and management practice in the areas of job design, motivation, and performance management. According to the feedback-seeking literature, when individuals are uncertain about how they are performing, they will engage in *feedback-seeking behavior*. Desiring information about how their performance is being perceived, they do not simply wait for feedback to be given to them; rather, they engage in active strategies to acquire that information on their own (and to reduce uncertainty).

Two different feedback-seeking strategies may be used, one direct and one indirect. The first strategy, referred to as *inquiry*, involves using direct verbal requests for performance information. For example, the employee may approach a supervisor or a coworker and ask, “What did you think about the proposal I pitched in the meeting yesterday?” The indirect method of seeking feedback, referred to as *monitoring*, involves scanning the organizational environment for information about how well one is performing. Monitoring tactics include listening to conversations, observing the performance or reactions of others, or using indirect questions to third parties to prompt feedback from relevant parties such as coworkers or managers. Although the obvious motivation to engage in feedback-seeking behavior is to acquire performance information and reduce uncertainty, there are other motivations as well, including ego defense and enhancement and impression management.

MOTIVATIONS TO SEEK FEEDBACK

Instrumental

The first motivation to seek feedback is instrumental. In the absence of feedback, employees will actively seek information that helps them evaluate how well their performance-related behaviors are contributing to important organizational goals. Employees use inquiry and monitoring as methods not only to determine which goals are important but also to evaluate how well their own performance is stacking up against these goals. Feedback seeking is most prevalent at times of uncertainty, such as when individuals are new to an organization and trying to “learn the ropes” and in situations of high role ambiguity.

Ego Defense and Enhancement

Because feedback is laden with positive or negative information and emotion, and because it comes from sources of greater or lesser influence, it can either threaten or enhance an employee's ego. Much of our self-concept comes from the feedback we receive from others; therefore, there is a natural human motivation to enhance and defend the ego in social settings. The need to maintain a positive self-image causes employees to pursue opportunities to maximize positive information and to minimize negative information about themselves. Research on feedback seeking reveals that employees tend to seek feedback when they believe they have performed well in order to verify their self-image or enhance their ego. On the other hand, when they believe that they have performed poorly, they are less likely to seek feedback and may even actively avoid it. This allows employees to minimize damage to their self-concept. The desire to seek ego-enhancing information and to avoid ego-threatening information is motivated not only by the desire for self-verification but also by the desire to make a positive impression on others.

Impression Management

Though workers sometimes are not sure of the quality of their performance, there are other times when they *are* sure that they have performed well. Several studies show that feedback-seeking behavior is often used as an impression-management strategy when individuals believe that their performance has been favorable and want others to notice. When the motive is to manage impressions, employees use feedback-seeking behavior not to *obtain* performance information but rather to *convey* or highlight performance information. When they believe that the act of feedback seeking and the resulting feedback elicited will be image enhancing, they will seek feedback from powerful others, usually their supervisors. They may inquire about their performance in exactly the same way they do when they are uncertain—for example, “What did you think of the proposal I pitched in the meeting yesterday?”—but this time believing that the proposal was brilliant and wanting to hear positive feedback about it.

When managers respond to the inquiry, they not only acknowledge that a strong performance was turned in but also experience a positive affective

response to the performance. Employees, then, succeed in making their good results salient, which, in turn, results in a positive impression on their managers. Thus, individuals tend to seek feedback shortly after a particularly good performance to highlight their success and to elicit positive reactions from their supervisors. The results of several studies support the idea that supervisors develop favorable impressions of individuals after delivering positive feedback and that individuals seem to be aware of this, thus increasing the motivation to use feedback-seeking behavior to make positive impressions.

On the other hand, employees have been shown to actively avoid feedback when they have performed poorly to reduce the chances that their supervisors will notice and, in turn, provide negative feedback. In particular, when supervisors react to poor performance with punitive, public, or overly emotional responses, employees learn to engage in active strategies such as concealing, hiding, or physical avoidance, so that a negative impression is not made.

Contextual Issues

There are many targets for feedback seeking available to employees, including managers, coworkers, employees, and customers. Research indicates that of all of these sources, employees place more importance on managerial feedback, presumably because managers have more direct control over formal performance evaluation and the distribution of rewards. Employees who have considerate and supportive managers are more likely to seek feedback than those who have leaders who react harshly and emotionally to bad news. In addition to leader characteristics, several other contextual conditions have been found to affect feedback-seeking frequency, including organizational norms for feedback seeking, perceived organizational support, and cultural differences in the appropriateness of feedback seeking.

At play in these different contexts is the extent to which there are “costs” associated with the act of feedback seeking, such as appearing weak or incompetent. For example, if a task is not going well and the employee is unsure of how to proceed, feedback seeking, though it may provide instrumental value, may also cause the supervisor and coworkers to believe that the employee is not competent to complete the assignment. Thus, the risk of inquiry might outweigh the benefits of the feedback in the employee's mind.

When the costs of inquiry are too high, individual performers may forego seeking feedback even though it could help them to improve their performance. Instead of approaching their managers, employees may choose instead to monitor the organizational environment for feedback or seek feedback from less threatening targets. Recent research indicates that poor performers may actively avoid feedback through strategies that minimize the chances that their poor performance will be discovered and that they will receive negative feedback.

FUTURE DIRECTIONS FOR RESEARCH ON FEEDBACK-SEEKING BEHAVIOR

Research on feedback-seeking behavior has been conducted for more than 20 years. Much has been learned, and the topic has gained more importance in an age in which knowledge workers go about their tasks in ambiguous environments, perhaps separated from peers, subordinates, and managers by geography, work-space, time, or culture. Many workers report receiving little or no feedback about their performance and may be more motivated than ever to seek out the information that they crave. Several aspects of feedback seeking have emerged as avenues for research in the literature, such as (a) how virtual workers seek feedback, (b) how feedback seeking occurs in cross-cultural settings, (c) the particular patterns of feedback seeking used by top managers, (d) the effects of learning goal orientation versus performance goal orientation on feedback-seeking behavior, and (e) the proactive strategies that poor performers use to avoid feedback from their managers. The continued interest in these topics ensures that the literature on feedback-seeking behaviors will continue to develop and provide us with meaningful insights into the fascinating cognitive, emotional, and behavioral processes of acquiring knowledge about one's performance.

FLEXIBLE WORK SCHEDULES

A flexible work schedule, also known as a *flextime schedule*, grants employees some freedom in deciding what time of day they will arrive at and leave from work. For example, an employee may prefer to work from 7:00 a.m. to 3:00 p.m. one day of the week and from 10:00 a.m. to 6:00 p.m. on another day. The exact administrative rules of flextime schedules vary greatly across companies, but when flextime schedules are put into place, employers usually create a band of core time during which each employee must be present (normally 9:00 or 10:00 a.m. to 2:00 or 3:00 p.m.). For example, a flexible work schedule in which all employees must be present from 10:00 a.m. to 3:00 p.m. would have five core hours. Employees are free to arrive before the core start time and leave after the core finish time, but typically, there is a limit as to how early employees can arrive and how late they can stay. For example, an employer may dictate that employees cannot start before 7:00 a.m. and cannot stay past 9:00 p.m.

Another important characteristic that may vary widely among flexible work schedule arrangements concerns the degree of carryover. Some organizations do not permit any carryover of hours (i.e., the employee must work eight hours per day), whereas others permit carryover on a weekly basis (i.e., no requirement for eight hours per day, but employees

must work 40 hours per week), and a few organizations even allow monthly carryover.

Recent surveys of the American workforce indicate that more than 25% of employees have the ability to change their daily work starting and ending times, and this number is increasing every year. Much of the increased offering or use of flexible work schedules is the result of societal changes (e.g., increasing numbers of women in the workforce, dual-career households). One can theorize that these changes have increased employee demands for flexibility in their work schedules so that they can better balance their work and family lives. Thus, flextime schedules are becoming more popular, and an increasing number of employees are making use of them.

However, a review of the literature reveals that certain segments of the population do not have access to flexible work schedules because of the industry they work in or the type of employment that they have (e.g., part-time versus full-time). For example, flextime schedules are used almost exclusively in non-manufacturing organizations. This may be attributable to the fact that a flextime schedule is more difficult to implement in continuous process operations such as assembly lines. Individuals who work part-time in any type of industry are much less likely to have access to flexible work schedules. Given that manufacturing and part-time jobs are less likely to offer flexible work schedules, it is not surprising to find that employees who are female, less educated, and non-White are also less likely to have access to flexible work schedules in the United States.

PERCEIVED BENEFITS OF FLEXIBLE WORK SCHEDULES

The reasons for the popularity of flexible work schedules are many and diverse but generally include a combination of personal, organizational, and societal gains that are presumed to derive from allowing workers to more effectively balance their personal lives with the demands of work. For example, the presumed positive effects of flexible work schedules include reduced commuter congestion, increased customer or client service, broadened work opportunities for employees, reduced amounts of work-family conflict, and better utilization of recreational and service facilities.

Several theoretical models are useful for describing how flexible work schedules affect important outcomes.

The *work adjustment model* has been used to explain how flextime schedules influence employees' attitudes and behaviors. This model suggests that a high correlation between an employee's abilities and the ability requirements of the job should lead to high role performance. Furthermore, a high correlation between an employee's needs and the reinforcement system of the work environment should lead to more positive job attitudes. Work adjustment is high when individuals fulfill their work and role requirements and when the organization simultaneously fulfills the needs of the individual.

Another theoretical model that can be used to explain the effects of flexible work schedules is the *job characteristics theory*. This model is based on the belief that the core characteristics of a job (e.g., autonomy, task identity) induce positive psychological states, which, in turn, lead to positive outcomes such as job performance and job satisfaction. For example, a flextime schedule should positively affect employees' sense of autonomy, thereby increasing job satisfaction. Using these models, several theoretical arguments can be made about the effect of flexible work schedules on some of the most important organizational outcomes: productivity and performance, absenteeism, and job satisfaction.

Using the work adjustment model, it can be hypothesized that flexible schedules allow employees to make more efficient use of their circadian rhythms (the normal 24-hour physiological cycle) and may decrease the amount of work-arrival-related stress that employees experience. Employees who make more efficient use of their circadian rhythms should experience a higher correlation between their abilities and the ability requirements of the job. Research on person-job fit supports the idea that congruence between the individual and the job environment leads to higher performance. Although the results of research on the relationship between job stress and job performance are mixed, it seems safe to assert that if reduced job stress leads to a reduction in negative reactions, then job performance can be expected to increase.

The implementation of a flextime schedule also gives employees more job autonomy. The job characteristics theory predicts that increased job autonomy should lead to increased job performance. Indeed, the research supports this relationship. In sum, with respect to productivity and performance, the introduction of a flexible work schedule can be expected to have positive effects.

Additionally, flexible work schedules should have an effect on employee absenteeism. Organizational attendance should increase as the amount of discretionary time increases. Employees working in an organization that offers a flextime schedule can more easily respond to work and nonwork conflicts, which can subsequently reduce employee stress; the research has linked decreased employee stress to decreased absenteeism. Motivation to attend work may also be enhanced by increased organizational loyalty and job satisfaction, which result from the implementation of a flexible schedule. Furthermore, it has been suggested that employees may no longer misuse their sick leave because they can adjust their time of attendance. Empirical studies support the hypothesis that attendance is positively affected by the availability of a flextime schedule, and organizations have reported dramatic drops in absenteeism. In sum, research and theory support the assertion that the introduction of a flexible work schedule will lower absenteeism.

Using the job characteristics theory, it can also be hypothesized that the introduction of a flextime schedule should lead to more positive job attitudes (e.g., job satisfaction). For example, employees' need for autonomy can be met by the introduction of a flextime work schedule; indeed, research has found that increased job autonomy is positively linked to job satisfaction. In sum, the introduction of a flextime work schedule can be expected to lead to increased job satisfaction and, more specifically, to satisfaction with one's work schedule.

REVIEW OF FLEXIBLE WORK SCHEDULE RESEARCH

Two comprehensive examinations of the flextime literature have been conducted. These narrative reviews concluded that the introduction of flextime work schedules has a consistent and almost exclusively positive effect on work-related attitudes and productivity. However, the effect of flextime schedules reported in the literature is still highly variable and ranges from little or no to substantial positive change. A quantitative review of the literature (i.e., meta-analysis) found that flexible work schedules have positive effects on employee productivity, job satisfaction, satisfaction with work schedule, and employee absenteeism. However, the size of these effects is significantly different from one variable to the next. For example, the effect associated with absenteeism is significantly larger

than that for productivity, and the smallest effects are seen for job satisfaction and for satisfaction with work schedule. This result is consistent with the hypothesis that flexible work schedules are more likely to influence attendance and retention than to directly affect worker effectiveness and attitudes.

The mixed results in the literature may point to the existence of factors that moderate the relationship between flexible work schedules and outcome measures. The same quantitative review mentioned found that several moderators exist. Specifically, flextime work schedules demonstrate positive effects on work-related outcome criteria for general employees, but they have no effect for professionals and managers. This finding suggests that alternative work schedules are unlikely to benefit those who already have a high degree of job autonomy. Flextime flexibility (measured by core hours) was also found to moderate the positive effects of flexible work schedules—that is, the positive effects seem to diminish as the number of core hours becomes smaller. This finding indicates that the positive outcomes expected from a highly flexible schedule may be offset by the extra control required to monitor the number of hours that employees work. Furthermore, it is possible that the increased flexibility may become more of an inconvenience for employees than a benefit. The meta-analysis also found that over time, the positive effects of flexible work schedules diminish.

Other research has found that employees' level of role conflict—that is, competing requirements between two roles, such as being an employee and a mother—also acts as a moderator and affects the way that individuals respond or are attracted to companies that offer flexible work schedules. Specifically, the study found that individuals with high role conflict are attracted to companies that offer flexible work schedules, but this is not the case for individuals with low role conflict. This suggests that individuals react differently to the introduction of a flexible work schedule, and this, in turn, affects the impact (on factors such as job satisfaction) that might be expected. For example, if an organization has many employees who do not experience role conflict, then the impact of a flexible work schedule would be expected to diminish.

SUMMARY

The narrative and quantitative reviews of the literature indicate that flextime schedules have primarily

positive effects on organizational outcomes. However, the literature also suggests that organizations will have varying degrees of success with flexible work schedules depending on the variables they are trying to influence (e.g., absenteeism versus productivity). Furthermore, organizations need to carefully examine the work that is being done by employees to determine the degree of interdependence among jobs. Offering too much flexibility to employees with highly interdependent jobs may lead to unexpected and unwelcome outcomes. Finally, the findings of the meta-analysis suggest that the positive effects of flexible work arrangements decrease over time; therefore, companies must realize that some of the benefits of flexible work schedules may be temporary.

that is designed to obtain perceptions about a defined area of interest in a permissive and nonthreatening environment. It can be used to explore a multitude of issues, and it is a very popular technique in the worlds of both market research and psychology. Although there is much to be said about focus groups, given their widespread use, three topics will be emphasize here: (a) focus group basics, (b) other important factors, and (c) applications of focus groups.

FOCUS GROUP BASICS

When conducting a focus group, four key factors must be considered: (a) the process, (b) the content, (c) group composition, and (d) data analysis.

With respect to process, a focus group ideally should consist of 10 to 12 people, although it certainly can be smaller or much larger. As Janine Waclawski and Steven Rogelberg (2002) note, it is typically led by a facilitator who asks the research questions and is assisted by a scribe who takes notes. It is vital that the focus group be led by both a facilitator and a scribe; one person alone cannot sufficiently manage the group, ask questions, probe for additional information, and capture session notes in real time. Although it is often tempting to consider streamlining the process to have one person performing both roles, this is not advisable under any circumstances. The duration of the focus group generally runs from one to two hours. In terms of location, a place where people feel that they can talk freely is best. This will lead to a better quality of data. For the most part, an offsite conference room is preferred. This typically engenders an environment of openness and fosters candid communication. These factors are critical to the success of a focus group.

According to some, including Krueger, the focus group can be as structured or unstructured as the facilitator desires. However, Waclawski and Rogelberg indicate that this is not considered best practice. Focus groups tend to run most smoothly and produce higher-quality data when the content of study is determined well in advance of the session. To accomplish this, most facilitators develop and use what is known as a *discussion guide*. This is a document that contains a scripted introduction to the session, the specific research questions to be posed to the group, and the session close. The introduction is important because it sets the tone and ground rules for the focus group. It typically contains a welcome statement; an introduction to the topic of the focus group; an introduction

FOCUS GROUPS

Focus groups are one of the fundamental qualitative data-collection tools used by industrial and organizational psychologists. According to R. A. Krueger (1994), a focus group is a carefully planned discussion

to the facilitator, scribe, and participants; and rules regarding the confidentiality of the data and the ultimate use of the results. The majority of the discussion guide focuses on the questions for the meeting and appropriate probes for follow-up.

No matter how well scripted the questions are, there is always some degree of fluidity and unexpectedness that occurs during the focus groups. This is normal and part of what makes this method of data collection so rich. The session close typically consists of a reiteration of confidentiality and the purposes for which the data will be used, as well as contact information for the facilitator.

Group composition is very important, and there are two options to consider: whether to select homogeneous (similar) or heterogeneous (mixed) participants. Homogeneous groups consist of participants who are similar on a set of dimensions that are viewed as critical to the results of the focus group. These are factors such as age, gender, education level, socioeconomic status, ethnicity, or geographic location. Conversely, heterogeneous groups consist of a mixture of participants who vary on these key dimensions. Although there has been considerable debate over the years as to which approach is better, current thinking supports the notion that homogeneous groups are preferable, as noted by Waclawski and Rogelberg. Quite simply, groups with similar participants yield more focused results, which is, after all, the purpose of the focus group. Furthermore, when a study is carefully constructed, a combination of different homogeneous groups will produce a heterogeneous mixture of participants.

The most common approach to analyzing focus group data is content coding. This consists of transcribing all of the notes from the focus group session, identifying major themes or content areas that are present in the data, and counting the frequency of responses for each theme (see Rebecca Morris's 1994 piece, cited in Further Reading, for an in-depth discussion of this process).

OTHER IMPORTANT FACTORS TO CONSIDER

On the surface, the conduct of the focus group and the analysis of focus group data may seem simple in comparison to other methods of research (i.e., those of a more quantitative nature). However, because focus groups are qualitative and somewhat subjective in nature, there are many nuances involved in mastering

this method of inquiry that can significantly influence the outcomes. In particular, the level of skill of the facilitator is crucial. An untrained or poorly trained facilitator will introduce experimenter bias, at best, and at worst, render the research completely invalid. For example, by directing the responses of the participants (as opposed to a more objective approach of teasing out responses), failing to solicit input from more introverted participants (allowing some strong members of the group to dominate), or allowing the group to go off on unproductive tangents, a poor facilitator can greatly affect both the session and the resulting data.

Maintaining consistent conditions across focus groups is also important to minimize unwanted error resulting from the effects of differing contexts. Using the same facilitator (or checking for interrater reliability when this is not feasible), the same discussion guide, and the same meeting setup is important to ensure similar experiences across focus groups. In the end, the details, no matter how small, are very important.

APPLICATIONS OF FOCUS GROUPS

Focus groups have many applications in the field of industrial and organizational psychology. They can be used either as a stand-alone research method or as an add-on to other methods. Focus groups are often used alone when the researcher wants to study a topic in depth with a group of individuals who can provide significant insight beyond what a traditional survey offers. They are often used to collect data on participant attitudes or opinions about a particular topic or a set of related topics. For example, an organization might conduct a focus group to assess its employees' level of satisfaction with its current benefits program, to find out whether employees trust senior management, or even to look at employees' attitudes and opinions about the recognition they receive for doing their jobs.

At other times, focus groups are used in conjunction with surveys (typically after the fact) to explore issues that were unearthed by the survey but not explained in sufficient detail to satisfy the researcher or to answer the research question at hand. Unlike a survey, the focus group enables an open dialogue between the researcher and participants, allowing important issues to be explored in depth. In this way, focus groups can be very useful, especially if the survey does not contain

any write-in or open-ended questions or if the results of the survey are unclear in some regard.

All in all, whether they are used alone or in conjunction with other research methods, focus groups are an extremely important applied research tool.

FRAME-OF-REFERENCE TRAINING

The appraisal of individual work performance occurs in some form or fashion in nearly every organization. Because these appraisals are typically used to provide feedback to employees and to make administrative decisions regarding promotions, bonuses, training, or termination, the quality of performance appraisals is an important issue in both research and practice. A number of approaches to ensuring the high quality of performance appraisal ratings have been researched and used in practice, including different types of performance appraisal instruments, methods, and rater training programs. Although many rater training programs have been developed, the program that has proved most effective in improving the quality of performance appraisal ratings is *frame-of-reference* (FOR) training. This method is designed to train raters (e.g., supervisors) to accurately assess a ratee's (e.g., subordinate's) performance according to the standards espoused by the organization. Here, we will explore what FOR training is, how it compares with other types of rater training, its effectiveness at improving the quality of

performance ratings, and research and practice issues related to FOR training.

FOR TRAINING DEFINED

One of Several Rater Training Programs

Several distinct rater training programs have been developed over the years, all with the goals of reducing rating errors and increasing rater accuracy. *Rater error training* has the explicit goal of decreasing common rater errors or biases (e.g., leniency or severity, halo, first impression, central tendency) by informing raters of these errors and how to avoid them. *Rater variability training* is similar in intent, with an emphasis on ensuring that the variability in ratings assigned corresponds to the variability in actual performance levels.

The early 1980s saw a shift away from training raters to avoid the types of errors just described to training based on a more proactive and direct emphasis on accuracy. This shift was partly the result of findings that suggested that training raters merely to avoid rating errors sometimes led to decreases in accuracy. Earlier forms of these training programs had included *rater accuracy training* and *behavioral observation training*, wherein much of the emphasis was on improving raters' detection, perception, observation, and recall (i.e., memory) of specific performance behaviors. These types of training programs encouraged the recording of behaviors to facilitate later recall and rating judgments. Another direct predecessor of FOR training was *performance dimension training*, which relied primarily on defining the important elements of performance for the raters. However, FOR training goes beyond this approach to provide an in-depth understanding of the organization's theory of performance, developed through interactive discussion, practice, and feedback.

Components of FOR Training

The main objective of FOR training is to provide raters with the knowledge and skills necessary to accurately rate performance according to an agreed-upon frame of reference. Through an interactive process, FOR training is designed to eliminate idiosyncratic standards held by raters and to replace them with a common frame of reference to be used in rating.

The FOR training process consists of four components. First, the trainees (i.e., performance raters) are familiarized with the target theory of performance through an informational presentation. This theory of performance, defined by the organization and therefore unique to the organization and to a particular job, includes the important dimensions (e.g., quality of work, taking initiative) that constitute the performance domain and their definitions. The rating scale to be used—a behaviorally anchored rating scale, or BARS—is usually presented at this time.

Second, trainees engage in a discussion of “critical incidents,” or specific ratee behaviors that indicate different effectiveness levels (e.g., high, average, or low) on each performance dimension, with reference to the BARS that contain these specific critical incidents as anchors at different scale points. For example, trainees might be told that if a ratee has no defects in his or her production, that is indicative of a *high* performance level on the quality-of-work dimension; if a ratee always waits to be told what to do at the beginning of his or her shift, that is indicative of *low* performance on the taking-initiative dimension.

Third, trainees are given practice rating using this new frame of reference. Specifically, trainees usually view several videotaped vignettes of ratees and rate the practice ratees on each performance dimension discussed in the training. Fourth and finally, trainees engage in a discussion of these practice ratings and receive feedback on the accuracy of their practice ratings (compared with expert scores).

Frame-of-reference training normally occurs over several hours within small groups (i.e., 5–12 trainees). In addition to the economic pragmatics of training more than one rater at a time, the presence of other trainees in a learning or performance situation is believed to increase attention level and motivation, and trainees can compare their practice ratings with those of the other raters, in addition to the expert ratings.

Effectiveness of FOR Training

Several research studies have examined the effectiveness of FOR training at improving performance rating accuracy, both in its own right and compared with other rater training programs. This research revealed strong and consistent evidence that FOR training is effective in this regard and, compared with other rater training programs, results in the largest overall increase in rating accuracy.

RESEARCH ON FOR TRAINING

With the effectiveness of FOR training established, research in this area primarily considers four major issues: (a) the extension of FOR training to other contexts; (b) the examination of underlying mechanisms that explain why FOR training is so effective; (c) the examination of which components of FOR training are most important to its effectiveness; and (d) possible boundary conditions on the effectiveness of FOR training. Each of these areas is briefly reviewed here, along with their corresponding implications for the use of FOR training in organizations.

First, regarding the extension of FOR training to other contexts, researchers have used FOR training in assessment centers with a great deal of success. Assessment centers are an in-depth assessment technique used to evaluate candidates (often managerial candidates) for hiring or promotion. Assessors observe and then rate candidates on different performance dimensions across a number of exercises. Providing FOR training to these assessors was found to result in assessment center ratings that were more reliable, accurate, and valid than other types of assessor training.

Second, one stream of research seeks to understand why FOR training is so effective at improving rating accuracy. Proposed explanations that have received some empirical support speculate that FOR training leads to deeper levels of processing of the material, better recall for specific performance behaviors, more accurate online impression formation, and systematic changes in the content of impressions formed of ratees (making their impressions more abstract and target referent) and that it requires raters to think seriously about the meaning of performance.

Third, because the FOR training protocol comprises several components, one stream of research has attempted to isolate which of these components is most important for improving rating accuracy. For example, the FOR training procedure can be broken down into the informational presentation alone (the dimensions and behaviors that indicate various effectiveness levels), the informational presentation plus practice (but with no feedback), and the informational presentation plus practice and feedback. Because this stream of research is still in its infancy, however, no unequivocal conclusions can be drawn about the most crucial components of FOR training or the possible synergies among them.

Fourth, although the vast majority of FOR training research supports the conclusion that it is effective at improving rating accuracy, some research has begun to recognize and examine possible boundary conditions on this effectiveness. For example, training effectiveness may depend on the extent to which a rater's performance theory is at odds with the theory espoused by the organization and taught in training. Differences in theory may create cognitive interference or motivational challenges for raters in training. In addition, although most research has found that FOR training results in accuracy improvements regardless of the specific accuracy index used (e.g., elevation, differential elevation, differential accuracy, or stereotype accuracy), other researchers have found that FOR training is more (or less) effective for some accuracy components than others. Such differential effects may have important implications for the use of FOR training in practice. Finally, the examination of FOR training and evidence regarding its effectiveness has been largely contained to laboratory (experimental) settings. The politics and pragmatics surrounding the appraisal of performance in real organizations may present another boundary condition on the effectiveness of FOR training.

G

GAINSHARING AND PROFIT SHARING

Gainsharing (GS) and profit sharing (PS) are two pay-for-performance systems used by organizations to reward workers for increased performance at the group, unit, or organization level (Rynes, Gerhart, & Parks, 2005). The ultimate goals of GS and PS plans are improving specific aspects of organizational productivity and improving employee attitudes relating to justice, collaboration, and teamwork. Successful group-, unit-, and organizational-level pay-for-performance plans incorporate the concept of *common fate*. Common fate is integral to the management of performance at the group, unit, and organizational level (Werther, Ruch, & McClure, 1986). The performance of an organization is seen as a direct function of the combined efforts of all its members. The margin of success for an organization, then, comes from replacing the adversarial relationship between management and employees with cooperation and collaboration. Workers who feel they have a stake in the company make contributions to the success of the company.

Gainsharing rewards employees for increases in efficiency on some important organizational criteria such as decreasing wastefulness and increasing productivity (Lawler, 1981). The typical GS plan is designed, using one of a number of formula variants, to be implemented within one facility such as one factory. Higher levels of performance are achieved through the involvement and participation of employees in some form of suggestion system (Lawler, 1981, 1988; Masternak, 1997). The two components,

monetary reward for improved efficiency and the use of participative management, are the defining components of a GS plan.

Profit sharing rewards employees for increases in organizational profits (Kruse, 1993). All PS plans have a formula specifying how a fixed percentage of organizational profits are divided among employees. Employee compensation is based substantially on the profitability of the company during some fixed time period. The typical PS plan is designed, using a number of formula variants, to be implemented within an entire corporation.

Both GS and PS plans have been shown to be effective. GS plans have been shown to result in labor cost savings of approximately 29% (Lawler, 1988). Rynes et al. (2005) write that PS plans, with a payout based on meeting a profitability target—such as return on assets (ROA) or return on investment (ROI)—have been shown to have a median effect of +4.4% and a mean effect of +7.4% on the criteria being used in the PS plan.

The most important difference between GS and PS plans is that the two types of pay-for-performance plans use different types of criteria to evaluate changes in performance for reward purposes. GS uses criteria that are focused on the internal efficiency of the organizational unit in which the plan is being implemented. For example, a GS plan may determine that the historical labor cost to produce one *widget* in the plant is \$5.00. Employees receive a bonus for lowering the cost of production of that widget. If the employees, through their suggestions and changes in work behavior, lower the labor cost to produce to \$4.50 per widget, the employees are rewarded for this

decrease in labor cost through the established GS formula. The criteria chosen for use in GS plans should be those which the employees of the organization may directly influence through changes in their behavior, or suggestions made, in the workplace. GS plans work only in situations where the inputs of employees are actually influential, and also in labor systems as opposed to capital-intense systems (Kim, 1999).

Lawler (1988) wrote that the mechanism by which GS plans increase organizational performance is proposed to be that GS plans

- establish the belief that rewards are based on improvement in performance on the organizational criteria being measured;
- establish ways for employees to influence organizational performance as measured by the reward system;
- provide feedback about organizational performance to employees; and
- create opportunities for employees to learn how to contribute to organizational performance.

Profit sharing plans use criteria that are focused on the external effectiveness of the corporation. The additional compensation received by employees is based on criteria (such as change in stock price, ROA, or ROI, which may be more related to factors outside the control of the organization than to the efforts of the employees of a company. For example, widget production may be linked to the cost of a raw material, *X*, which is required to produce the widget. If the price of *X* rises, the company may not be able to pass all the cost of this rise to its customers and profits will fall. If the price of *X* decreases, the company may be able to keep the widget price for consumers at the same level, and more profit is generated. In each case, however, the efforts and inputs of the company's employees are irrelevant to the amount of profit generated. The mechanism through which PS plans improve performance is, therefore, less clear than for GS plans. In fact, PS plans may not be appealing to some employees because they do not know how their behavior contributed to the profits of the company (Stack, 1996; Kraizberg, Tziner, & Weisberg, 2002).

This leads to a second important difference between GS and PS plans. Gainsharing programs always are implemented in conjunction with some form of participative management (e.g., a suggestion

system), whereas PS plans usually do not have a participative system associated with them (Lawler, 1988). This may be the result of the way PS plans allocate additional compensation. Employees have less input in PS plans because they are being rewarded for changes in externally focused criteria that are not under their control.

One decision that must be made during the planning and implementation process is related to choice of the variant to be used whether a GS or PS plans is being considered. Variants differ on both the degree of participation by employees and the formula to be used in GS plans (Bazerman & Graham-Moore, 1983; Welbourne, Balkin, & Gomez-Mejia, 1995). There is no clear distinction among the GS variants such as Scanlon, Rucker, or Improshare plans for effectiveness. Similar problems exist for choice of appropriate variant in the implementation of PS plans (Kruse, 1993). For PS plans, however, the variants deal more with the way employees are compensated. There are three basic forms of PS plans. First, PS plans may provide cash (employees have their share of profits added directly to their paychecks at quarterly or annual intervals). Second, PS plan profits may be deferred (the profit share amount is put into a pension trust for the employee and received by the employee on retirement). Finally, PS plans may provide both cash and deferred benefits in some combination. Kruse (1993) wrote that the variant of PS chosen is related to the effectiveness of the program. Cash plans are more effective than the other forms of plans in improving employee perceptions of teamwork and collaboration in a company.

One key variable in the development of perceptions of common fate critical to the success of a pay-for-performance program at the group, unit, or organizational level is the size of the organizational unit in which the plan is implemented. The size of the facility covered by a GS plan is usually small (Lawler, 1981). According to White (1979), GS plans such as the Scanlon Plan can be implemented without size limiting possible success for companies of up to 600 employees. In a review of the Shultz study, Schuster (1983) found that only 3 out of 21 companies using GS plans had 1,000 or more employees and the median number of employees per company was 201 to 500. Kruse (1993) wrote that these numbers are similar to those found for PS plans. Average productivity increases are larger for smaller companies: The highest improvements in PS plans are found for

companies smaller than 775 employees (Rynes et al., 2005).

An interesting paradox exists in the study of the effects of both GS and PS programs on organizational performance. Lawler (1988) wrote that moderators of the success of GS plans include a climate of trust between labor and management; and Kim (1999) noted that success depends on whether or not the company is financially sound and able to make reward payments. Similarly, PS plans work better in companies that have shown an increase in stock price over the preceding two years (i.e., are generating a profit) (Kruse, 1993).

Lawler (1988) suggested that if companies are high on the two moderators listed for GS, they will not stand to gain a lot from implementing a GS plan. It is likely that this proposal holds for PS plans as well. Therefore, one key issue that remains to be resolved for both GS and PS plans is whether the GS or PS plan is a cause of organizational performance or an effect of organizational performance (Lawler, 1988; Kruse, 1993).

GAY, LESBIAN, AND BISEXUAL ISSUES AT WORK

Gay, lesbian, and bisexual (GLB) individuals are physically and emotionally attracted to individuals of their own gender. These individuals compose a substantial proportion of the workforce (estimates range from 5%–15%) but face unique challenges because of their sexual orientation. Consequently, researchers and practitioners in industrial/organizational (I/O) psychology have begun to develop frameworks for considering GLB issues in the workplace, investigating challenges facing GLB employees, and discussing strategies for the equitable and effective management of sexual orientation diversity.

A STIGMA FRAMEWORK

Although a GLB identity is a positive and proud identity for some people, it is often deemed a devalued social identity in the larger societal context. Consistent with a conceptualization of stigma, GLB individuals are targets of negative stereotypes, social isolation, and discrimination. Accordingly, we use stigma theory and research to understand the experiences of GLB individuals at work. In fact, many of the issues facing GLB employees emerge as a function of the stigmatization of homosexuality in contemporary American society.

There are a number of dimensions on which stigmas are categorized, including three that are particularly important characteristics relevant to understanding the GLB stigma: controllability, concealability, and fear of contagion. First, controllability refers to the fact that the stigma of homosexuality is largely perceived to be a volitional choice and a controllable condition. Across stigmas, perceived responsibility is associated with negative attitudes and increased discrimination toward those who are stigmatized—particularly increased hostility, decreased sympathy, and motivations to avoid.

Second, the concealability of the GLB stigma refers to the fact that most GLB individuals can choose to conceal or reveal their sexual orientation. Given the fact that most gay and lesbian employees can *come out of the closet*, they face disclosure dilemmas in the workplace. They must decide if, when, how, and to whom they should disclose their orientation. Some decide not to disclose to anyone, whereas others decide to disclose to a trusted few or to everyone. Unfortunately, sometimes GLB individuals report being *outed* or having their identities disclosed without actually choosing to do so themselves. For the most part, the concealability aspect sometimes necessitates that individuals spend a great deal of energy and preoccupation managing their identity, and such a situation contributes to challenges for GLB employees and their organizations.

Third, fear of contagion refers to the fact that many people perceive that the GLB identity is threatening. Those interacting with GLB individuals face the possibility of being stigmatized (and perceived as GLB themselves) simply for associating with GLB individuals. In addition, because of its historical linkage with HIV-AIDS, the GLB orientation is perceived to be a contagious one possibly resulting in disease and even death. Given these associations, many individuals prefer to sever ties with GLB individuals.

There are individual differences that lead some employees and organizations to display particularly negative attitudes and behaviors against gay men and lesbians. In general, women tend to be more accepting of the GLB identity than men; and as a result, women are much less likely to show prejudice and discriminate. In addition, people who are more conservative and religious are also more likely to discriminate against gay men and lesbians. The stigma framework and the association of homosexuality with controllability,

concealability, and contagion helps I/O psychologists examine the challenges faced by GLB employees and their organizations.

GLB CHALLENGES AT WORK

In considering GLB issues in the workplace, it is important to examine the challenges that organizations face as well as the issues that affect GLB employees on a personal level. As bearers of social stigma, GLB employees are likely to face discrimination. Because discrimination on the basis of sexual orientation remains legal, there are few legal actions that GLB employees can take when they face stigmatization. In fact, there have been some highly publicized and recent instances of individuals losing their jobs (e.g., those in the military, leaders of churches, leaders of children's groups such as the Boy Scouts) when their sexual orientation is revealed. Fortunately, many of these sanctions are now being challenged in the court system, and some local and city ordinances are trying to combat such discrimination. In fact, research suggests that because of pressure toward political correctness and genuine attitude change, discrimination toward GLB individuals is typically manifested in subtle, rather than overt, behaviors. That is, instead of blatantly discriminatory actions, sexual orientation discrimination may take the form of negative nonverbal behaviors including decreased eye contact and increased interpersonal distance and social isolation.

In addition to discrimination, GLB individuals face the challenge of the *disclosure dilemma*. GLB employees who elect to disclose their sexual orientation in their workplace may fear the possibility of becoming the targets of harassment. Moreover, they may fear that such disclosure could even lead to the termination of their employment. However, when GLB employees elect to keep their sexual orientation a secret, they might face other possible negative outcomes. Research suggests that the stress of keeping their personal lives secret at work may negatively affect employees' levels of stress, immune systems, and loyalty to their organizations. Therefore, GLB employees face a double-edged sword in their decision to conceal or disclose their sexual orientation. Even when the challenge of disclosure is overcome, GLB employees have to negotiate the integration of their work and nonwork lives. For example, openly gay employees must decide whether to bring their partners to company social functions, to display their

partners' photos on their desks, or even to discuss weekend plans with coworkers and supervisors. These decisions are persistent, salient challenges facing GLB individuals at work every day.

From the perspective of organizations that employ GLB individuals, additional challenges arise. Broadly, organizations must decide how to manage sexual orientation diversity. Specifically, organizations and organizational leaders must examine the formal policies and informal organizational climate for GLB issues. Organizations must decide whether to introduce formal policies that support GLB employees or ignore sexual orientation as a diversity characteristic in organizational policies. In addition, organizations must determine the extent to which they will work toward creating a supportive informal climate for sexual orientation diversity. The consequences of formal and informal efforts to support sexual orientation diversity create additional challenges.

On the one hand, when organizations elect to include sexual orientation in nondiscrimination policies, they must be prepared to encounter employees who are unwilling to accept or comply with those policies. On the other hand, failure to include such policies may result in dissatisfied GLB employees, high turnover rates, and potential litigation. Successful implementation of sexual orientation diversity programs and policies will likely depend on top management support and employee buy-in. Further, although such formal policies might protect GLB employees from overt forms of discrimination, organizations may still face the challenge of eliminating subtle, interpersonal forms of discrimination. Thus efforts to reduce GLB discrimination in the workplace must be developed and evaluated carefully.

IMPROVEMENT STRATEGIES

There are clearly strategies individuals and organizations can adopt to reduce GLB discrimination. Ideally, the burden of reducing discrimination should not be on the victims but, rather, should live with the stigmatizers themselves. However, it is important to note that GLB individuals, their coworkers, and the organizations of which they are a part can engage in behaviors that can alter the course of prejudice. At the individual level a growing body of research has shown that disclosing one's GLB status can be a beneficial strategy but only given certain conditions. For example, research suggests that organizational climates that are

supportive, waiting a delayed period of time before disclosing, and ensuring some degree of coworker support are hugely predictive of positive *coming out* experiences. Other research shows that employers may be particularly likely to stigmatize GLB employees when little is known about them other than their GLB status. Thus GLB individuals who try to individuate themselves or who provide employers and coworkers with a body of information (that is typically unrelated or counter to GLB stereotypes) and reveal their strengths and skills as employees can allay others' inclinations to discriminate. Another strategy that GLB individuals might use is to compensate for the prejudice that they believe others will show toward them. Compensation typically involves verbal behaviors such as listening skills and nonverbal behaviors, including eye contact and nodding, that focus on conversational maintenance and continuation, all of which also attempt to put interaction partners at ease.

At the organizational level, there are a number of strategies that institutions can adopt to reduce discrimination toward GLB employees. Many strategies involve the implementation of formal GLB-related policies. For example, institutions that adopt same-sex partner benefits, diversity training programs with a focus on appreciation for sexual orientation diversity, diversity officers, GLB support groups, and antidiscrimination policies are all more likely to result in more satisfied GLB employees. Such formal steps are also likely to lead to a more accepting informal climate. Research reveals that much discrimination occurs at the interpersonal level and the institution of formal policies likely sends a clear message to employees about the culture and the message that interpersonal discrimination is not tolerated. Moreover, because much of the discrimination does occur at the interpersonal level, it is important to promote supervisor and coworker support of GLB employees. Such support has been shown to be particularly likely to result in more favorable outcomes for GLB employees.

CONCLUSION

GLB issues are, and will continue to be, important to organizations. It is hopeful that as more employees disclose their sexual orientation identities and as more organizations implement supportive policies, pressure on lobbyists and lawmakers will eventually afford GLB individuals with liberties and legal rights that are

now denied to them. To some extent, great strides have already been taken to reduce the stigmatization of GLB individuals. One important example of such change is the removal of homosexuality as a disorder from the *Diagnostic and Statistical Manual of Mental Disorders, 4th Edition (DSM-IV)*. Researchers and practitioners should build on this growing body of knowledge and use it to work toward allowing GLB individuals full and nondiscriminatory participation in society. When managed equitably and effectively, diversity, in all its forms, can benefit both employees and their organizations.

GENERALIZABILITY THEORY

An important criterion on which psychological measures are judged is the degree to which their scores reflect persons' true standing on an attribute of interest, such as cognitive ability and conscientiousness. Measurement theories recognize that scores on a

measure reflect at least two components: a *true* component and an *error* component. Although theories differ in terms of the way they define these components, the degree of relation between them, and the types of error on which they focus, they all share a concern for measurement error. Generalizability theory (G-theory) is a measurement theory that provides methods for estimating the contribution of multiple sources of error to scores and quantifying their combined effect with a single index—a generalizability coefficient (G-coefficient).

FUNDAMENTALS OF G-THEORY

At the root of G-theory is the idea that the variability in persons' scores because of error (i.e., *error variance*) can be partitioned into components, each reflecting a different source of error. For example, in attempting to measure a person's level of interpersonal skill using an interview, error might arise from

- the specific question asked, such as differences in how interviewees interpret the question;
- the specific interviewer conducting the interview, such as differences in the familiarity of the interviewer with each interviewee; and
- the particular occasion on which the interview was conducted, such as the mood of the interviewee on the day of the interview.

All the differences noted previously could influence a person's interview score for reasons that have nothing to do with the person's interpersonal skills. By taking a fine-grained approach to examining error, G-theorists gain critical insight into the factors that decrease the quality of their measures.

Partitioning Variance in G-Theory

Within G-theory, variance in scores is typically partitioned through analysis of variance (ANOVA). The type of ANOVA conducted follows from the *measurement design*, which describes how a given attribute is measured. G-theorists describe measurement designs in terms of *facets of measurement*—the set of measurement conditions under which data on the *objects of measurement* (the entities being measured) are gathered. Continuing with the interview example, facets of measurement might include questions, interviewers, and occasions; whereas the objects of measurement would be interviewees. In

G-theory, facets and objects of measurement serve as *factors* in an ANOVA model that is used to generate estimates of their contributions (as well as their interactions' contributions) to variance in scores.

Defining True Variance and Error Variance in G-Theory

Estimates of variance attributable to the object of measurement, facets, and their interactions are often referred to as *variance components*. The variance component associated with the object of measurement is interpreted as an estimate for *true* variance—the amount of variability in scores that is attributable to differences between objects of measurement such as interviewees on the attribute of interest including interpersonal skill. G-theorists refer to such variance as *universe score variance*. Whether a particular variance component is interpreted as error depends on the types of inferences the researcher wants to draw regarding the objects of measurement and the facets of measurement across which the researcher wants to generalize scores.

To illustrate this dependence, consider the interview example discussed earlier. If inferences are restricted to the relative ordering of interviewees on interpersonal skill, only those sources of variance that lead to different orderings of interviewees on interpersonal skill would be defined as error. In G-theory such error is referred to as *relative error*. Relative error is evidenced by interactions between the objects such as interviewees and facets including questions and interviewers of measurement. For example, the larger the interviewee-by-question interaction, the more the relative ordering of interviewees on interpersonal skill differs depending on the question asked. When error is defined in relative terms, G-coefficients reflect the consistency with which the objects of measurement are ordered on the attribute of interest across facets such as interview questions, interviewers, and occasions. Technically, a G-coefficient is defined as the ratio of universe score variance to universe score variance plus error variance, and it ranges from 0 to 1.

Alternatively, someone might wish to make inferences about persons' true standing on some attribute compared with a fixed standard such as a cut score or performance standard. Such absolute comparisons are labeled *criterion-referenced* comparisons. In this case any source of variation causing an observed score to differ from a true score would be defined as error. In

G-theory this type of error is referred to as *absolute error*. Absolute error includes not only interactions between of the objects and facets of measurement but also *main effects* of the facets (e.g., variation in mean interpersonal skill scores across questions because of differences in question difficulty). Facet main effects do not contribute to relative error because they do not affect the relative ordering of objects of measurement; rather they only affect the distance between objects' observed scores and true scores. When error is defined in absolute terms, G-coefficients (often called *phi-coefficients* when error is defined in absolute terms) reflect an estimate of absolute agreement regarding the standing of the objects of measurement on the attribute of interest across facets of measurement.

Decisions regarding which sources of variance are defined as error also depend on the facets across which the researcher wishes the scores to generalize. Returning to the interview example, to generalize interpersonal skill scores across questions, any inconsistency in the relative ordering of interviewees (or in mean score differences, if absolute error is a concern) across questions would be considered error.

Although the aforementioned example describes generalizing across a single facet (i.e., questions), there may be a need to generalize across other facets as well, such as interviewers. When considering two or more sources of error, there is the potential for interactions between the sources. For example, an interviewee's interpersonal skill score may depend not only on the question used to assess interpersonal skill but also on the specific interviewer who rated the interviewee's response to that question such as an interviewee-by-question-by-interviewer interaction.

Limitations in Measurement Designs

A key insight made clear by G-theory is that not all measurement designs allow researchers to estimate the sources of error that may be of concern to them. For example, assume that in implementing the interview described previously, the same interviewer conducts one interview with each interviewee. Although error may arise from the particular interviewer used, as well as the particular occasion on which the interview was conducted, it is not possible to estimate the contribution of these sources of error to observed interview scores based on this measurement design. To determine whether the relative ordering of interviewees on interpersonal skill differs across

interviewers or occasions, obtain ratings for each interviewee from multiple interviewers on multiple occasions. Thus the fact that this particular measurement design only involved one interviewer and a single administration of the interview prevents assessing the generalizability of interview scores across interviewers and occasions.

The measurement design in the aforementioned example is also problematic in that the estimate for true variance in interpersonal skill (if variance in observed interview scores were decomposed) partially reflects variance arising from the interviewee-by-interviewer and interviewee-by-occasion interactions. To eliminate the variance attributable to these interactions from the estimate of true variance requires multiple interviewers to rate each interviewee on multiple occasions. Thus just because a given measurement design prohibits estimating the impact of a source of error on observed scores does not imply that the error is eliminated from a measure. Indeed, the error is still present but *hidden* from the researcher's view and, in this example, inseparable from the estimate of true variance.

G-THEORY AS A PROCESS

When introduced by Lee J. Cronbach and his colleagues more than 40 years ago, the application of G-theory was conceptualized in terms of a two-step process for developing and implementing a generalizable measurement procedure. The first step in the process is to conduct a *generalizability study* (*G-study*). The purpose of the G-study is to gather data on a given measure using a measurement design that allows the researcher to generate estimates of all error sources of concern (and therefore avoid limitations raised in the previous section). With such estimates, the researcher could estimate what the generalizability of the measure would be under various potential measurement conditions. For example, based on findings from the G-study, researchers could estimate the number of observations needed for each facet of their measurement design (e.g., number of questions, interviewers, occasions) to achieve a desired level of generalizability in their measure. The second study, called a *decision study* (*D-study*), would involve implementing the measurement procedure identified via the G-study to gather data on the persons for whom decisions are to be made.

Although practical constraints often obviate this two-stage approach, it can have substantial value for

improving industrial/organizational (I/O) research. Specifically, it forces researchers to give forethought to, and acquire knowledge of, the sources of error that are of concern to them in their measures. With such knowledge researchers can take steps to improve measurement procedures by identifying where refinements might have the most impact (targeting the largest sources of error) prior to having to implement their measure to make real decisions (e.g., whom to hire, whom to promote). In other words, G-theory offers a clear process for building improved measures.

GENETICS AND INDUSTRIAL/ ORGANIZATIONAL PSYCHOLOGY

The idea that genetics may play a determining role in work behavior and work-related phenomena does not have a particularly long past in terms of actual research activity among industrial/organizational (I/O) psychologists. Whereas research in other domains of psychology convincingly have shown that human

behavior is influenced by genetic and biological characteristics of individuals, it was only within the past 10 years or so that researchers in the organizational domain have developed evidence that traits, attitudes, and behaviors relevant to the workplace also have a genetic component. There are essentially two streams of research that have pursued this issue. The first stream stems from I/O psychologists writing in the area of evolutionary psychology, where arguments are made that certain differences between individuals or classes of individuals have an evolutionary explanation. For example, several I/O psychologists have presented the argument that sex differences in power are caused by differences in the way men and women use influence behaviors in small groups and that these differences were sculpted in part by natural selection. Others have made the case that organizational processes and behavior have been developed via evolutionary history. Essentially, the argument is that through natural selection, sexual selection, and adaptation, a wide range of psychological phenomena (e.g., behaviors, attitudes, traits, decision-making styles, etc.) in humans and relevant to the workplace have evolved and can be explained via this genetic process. In fact, a special issue of the *Journal of Organizational Behavior* has been organized around the issues of evolutionary processes as they influence organizational phenomena.

A second stream of research has also been *evolving* over the past few years: the application of behavioral genetics methodologies to the study of workplace outcomes. Behavior genetics is essentially the exploration of the relative contributions of genetics and the environment to human behavior. Whereas evolutionary psychology is essentially theory based and provides logical explanations for why certain work phenomena may exist, the application of behavior genetics methodologies helps to provide *empirical data* for exploring the role of genetic and environmental factors in workplace phenomena.

BEHAVIOR GENETICS METHODOLOGIES

There are several research designs used in estimating the role of genetics by researchers in the behavior genetics arena. Most researchers use twins as their subjects by examining the similarities and differences between identical (or monozygotic) and fraternal (or dizygotic) twins. Because identical twins share 100%

of their genes in common and fraternal twins share an average of 50% of their genes, the greater similarity in identical twins than in fraternal twins on any measured variable is a sign that genetic influences are involved. This design assumes that the two twin types share approximately the same common environment in their early developmental lives; that is, that each twin pair experiences the same global family *treatments* such as income levels, books in the household, and similar treatment by mothers and fathers; and such factors did not produce greater similarity among the identical twins. Sophisticated statistical methods are now used to not only determine if variables are under some genetic control but also to estimate the proportion of variance attributable to genetic factors, as well as to common family and nonfamily environmental factors. Another design that is used, but rarely, is the use of identical twins who were separated at birth and raised apart. Because they were raised in different and independent environments, the similarity of such twins is also an indicator of genetic influence. Researchers also use adoption studies where the relative similarities of adopted children to their biological and adoptive family members are used to estimate genetic influences; however, this design has not been used by I/O psychologists as of yet. Results of studies employing these various methodologies typically report findings in the form a *heritability* value ranging from .00 indicating no variance in a variable explained by genetics to 1.00 where 100% of the variance is accounted for by genetics. (Obvious physical characteristics such as height and weight show high heritabilities and might be used as a *benchmark*.) Finally, research methods using path modeling techniques where the relationships between specified variables have been derived via meta-analytic procedures are now being used to derive heritability estimates.

BEHAVIORAL GENETICS RESEARCH AND ORGANIZATIONAL BEHAVIOR

Researchers in the I/O area have been interested in the role of genetics as they influence certain classes of constructs: traits, attitudes, values and interests, affect, and behaviors. Two reviews are available that provide more comprehensive information about research in these areas (Arvey & Bouchard, 1994; Ilies, Arvey, & Bouchard, in press). Following is a summary of these findings.

General Cognitive Ability (GCA)

Where estimates of genetic influences on general cognitive ability (GCA) in the reported literature vary considerably, there is little debate on whether such genetic influences exist. Estimates are that the heritability of intelligence falls somewhere between .50 and .80. There is also evidence that the heritability of IQ increases with age.

Personality

Numerous studies have been conducted on the heritability of different personality traits or dimensions. Industrial/organizational psychologists have been interested in personality traits as predictors of other work behavior and frequently have adopted a five-factor model of personality termed the *Big Five*. Research dealing with these Big Five factors show relatively high and consistent heritabilities. For example, using data and research reported in several behavioral genetics studies conducted in multiple countries, J. C. Loehlin (1992) estimated the heritabilities as .41, .49, .45, .35, and .38 for emotional stability, extraversion, openness to experience, agreeableness, and conscientiousness, respectively. Also, evidence for the heritability of affective traits has accumulated where heritabilities of .50 and .44 were found for the trait measurement of positive and negative emotionality.

Attitudes

An early application of behavioral genetics methods for estimating the heritability of job satisfaction was presented by Arvey, Bouchard, Segal, and Abraham (1989) using a sample of twins reared apart. Their data showed that genetic factors explained approximately 30% of the variance in job satisfaction scores, but this result did not go unchallenged. This finding was replicated later by Arvey and colleagues as well as other researchers.

Work Values

Research has also been conducted examining whether genetic factors are associated with work values. Results from one study showed that five value constructs (achievement, status, altruism, safety, and autonomy) had heritabilities ranging from .18 to .56, with a median of .38. The findings from this study have also been replicated.

Leadership

The issue of whether leadership is a function of genetics has been around for a long time—the famous *nature versus nurture* debate. Behavioral genetics methods have just begun to explore this issue scientifically. One group of researchers showed that a substantial proportion of the variance in transformational and transactional leadership is associated with genetic factors. A more recent study using a sample of more than 300 twin pairs estimated the heritability of occupational leadership achievement—that is, whether individuals were actually in formal positions of leadership—and found it to be around .30. Research around the issue of whether genetics interacts with specific environmental features to influence leadership is ongoing.

Performance Behaviors

There has been some research on the heritability of counterproductive work behaviors. One study using a male twin sample explored whether a scale called Censured Job Performance, consisting of items associated with counterproductive work behavior and low job performance (reprimands, probation, or performance-related dismissal), was heritable; the resulting heritability was .37.

MEDIATION AND INTERACTION MODELS

Most researchers using behavioral genetics methods and models agree that it is quite unlikely that any specific one gene, or even several, have a direct impact on work behavior; that is, they don't directly influence work attitudes or behavior. Instead, these researchers posit models where the genetic aspects of individuals may have more broad impact on attraction: avoidance patterns, which in turn, over time, help to shape more specific behavior and attitudinal dispositions. There has been some investigation into whether personality and cognitive variables mediate the relationships between genetic factors and other work phenomena such as leadership and job satisfaction. For example, one study examined whether the Big Five personality factors are primarily responsible (through mediation) for the genetic influences of job satisfaction using path analysis of meta-analytic correlations. Although the authors found that these factors mediated only 24% of the genetic variance in job satisfaction, the

affective traits of positive and negative emotionality mediated 45% of the genetic effect. These authors made the observation that broader and more abstract constructs seem to be more influenced by genetic factors than narrower and more specific constructs. More research of this nature is needed to further pin down just how genetic factors operate to influence work and organizational constructs.

Researchers in this area have also called for more investigation to determine with greater specificity which environmental factors influence organizational phenomena as well as whether there are important interactions between features of the environment that interact with genetic structures to effect work phenomena. This would be important information for I/O psychologists in terms of engineering environments that might have greater (or lesser) impact on individuals working in organizations.

SUMMARY

Although the study of genetics with regard to work-related phenomena is in an infant stage, research is accumulating at an increasing rate. Compared with what we knew 10 years ago, the frontier of this particular field is growing at a rapid pace. New methodologies and statistical models are being applied. Results from the established literature base make it clear that biological mechanisms and certainly genetic influences play a role in determining work behaviors in the form of personality, cognitions, attitudes, and the behavior of individuals in work settings.

GLASS CEILING

The glass ceiling has been defined by the U.S. Department of Labor as artificial barriers based on attitudinal or organizational bias that prevent qualified individuals from advancing upward in their organization into management-level positions. The concept of a glass ceiling was originally used to describe women's blocked opportunities within organizations and has also been applied to the experiences of ethnic minorities. It is commonly referred to as the barrier that cannot be seen or touched but has the effect of stopping women and minority members from reaching the top echelons of organizations. For example, there are increasing numbers of women and ethnic minority members in management in general. However, they are not proportionally represented in the top management positions.

Research on the glass ceiling spans many disciplines, including sociology, psychology, management, gender studies, and ethnic studies, just to name a few. The bulk of the early research focused on documenting and reviewing the status of White women's progress into management. Research, predominately in the form of reviews on the glass ceiling, began in the mid-1970s. These reviews addressed the question of why there were so few women in management positions within organizations. As the number of women in the labor force increased over time and women advanced into management ranks, the issue of concern became one of why there were so few women in top management positions.

Currently, the number of women in top management is still not proportional to their representation in management overall. The most recent Census of Women Corporate Officers and Top Earners conducted by Catalyst in 2002 found that women currently represent 15.7% of corporate officers in America's Fortune 500 companies. This was an increase from 12.5% in 2000 and 8.7% in 1995. Women compose 7.1% of the 496 chief financial officers (CFOs) and 16.1% of the 453 general counsels (GCs), an increase from the year 2000, when 5.6% of the CFOs were

women and 13.7% of the GCs were women. Despite the increased number of women in the upper echelons of Fortune 500 companies, the top earning corporate officers were predominately men; 95% ($n = 2,141$) were men, whereas 5.2% ($n = 118$) were women. Women were far less likely to be in line positions, meaning those positions with revenue-generating or profit and loss responsibilities that tend to lead to advancement and greater rewards, than men at 6.2% versus men at 93.8%. Women have made some progress in catching up with their male counterparts, but disparities in power and salary still exist, leading to the assumption of the existence of the glass ceiling for women.

In recent years, as ethnic minorities have entered into the ranks of management and in increasing numbers into the labor pool, it has been suggested that they also encounter a glass ceiling. For example, population statistics and research show that minorities have less access to well-paying jobs, have few opportunities for promotions, and are segregated into less prestigious occupations or niches within occupations. However, most research on the glass ceiling and minorities has focused predominately on African Americans, to the exclusion of other minorities. African Americans are currently the largest numerical ethnic minority in the United States and correspondingly has been the most studied minority group. Recently, it has been suggested that not all ethnic minorities encounter the same type of barriers because of differences in experiences specific to each ethnic minority group. For example, Asian Americans as a group currently have the highest educational attainment levels and are well represented in professional and technical fields. It has been suggested that they may encounter different types of barriers than African American minority members. More research focusing on other ethnic minority groups is needed to investigate these hypotheses.

There have been multiple theoretical perspectives offered to explain the disparities that lead to a perceived glass ceiling effect for women and minorities. Individual explanations such as human capital theory (Becker, 1975), work–family differences, and sex differences in leadership styles have all been proposed to explain the disparities in career outcomes. The idea that women and minorities possess less human capital (education, experience, etc.); have different priorities when it comes to work–family balance; or exhibit less

effective leadership styles, which results in slower advancement, has not been consistently supported by research. There is general consensus that these individual characteristics approaches are useful in explaining some aspects of inequality, but they are insufficient in accounting for the myriad factors leading to a glass ceiling for women and minorities.

Organizational factors such as exclusion from informal networks, less availability of powerful mentors, and lack of proper socialization have also been posited to explain differential career outcomes. These organizational factors have been shown to put women and minorities at a disadvantage in moving upward within an organization. Access to informal networks and mentors has been shown to be positively related to upward mobility, higher salaries, and more promotional opportunities. It has been found that women and minorities have less access to powerful mentors who are in positions to help them advance. In addition, women and minorities report exclusion from informal networks in organizations, which are pivotal in increasing visibility and building contacts. These organizational factors are viable reasons that lead to slower promotional rates for women and minorities and contribute to a glass ceiling effect.

There is also a structural barriers explanation for the glass ceiling effect. This focuses on the different facets of labor market discrimination, in which there are dual labor markets with minorities and women relegated to the peripheral labor market and White males dominating the core labor market. The core labor market is characterized by high wages, good fringe benefits, job security, and advancement opportunities. The peripheral market consists of lower paying, less desirable work of lower prestige and an absence of internal labor markets to facilitate upward mobility or long-term growth. It is thought that segregation of women and minorities into the peripheral labor market results in differential rates of advancement and rewards throughout their careers.

There is little argument that women and minority members are not as well represented at the highest levels of organizations as their numbers in management overall or the labor pool would predict. Recent years have witnessed gains made by women and minority members. Still, there seems to be evidence that a glass ceiling still exists for both women and minorities, but the exact causes and therefore a solution

are still undeterminable. Multiple factors at the individual, organizational, and structural levels seem to interact in forming a glass ceiling for women and minorities at this time.

GLOBAL LEADERSHIP AND ORGANIZATIONAL BEHAVIOR EFFECTIVENESS PROJECT

The Global Leadership and Organizational Behavior Effectiveness project (GLOBE) is a multiphase, multi-method project designed in the early 1990s by Robert J. House to explore the relationships among societal culture, organizational culture, and leadership. An international team of more than 170 researchers has worked together for more than a decade on this project.

Many data sources were used to obtain information regarding organizational culture, societal culture, and leadership attributes and behavior. The primary data source was questionnaire responses completed by approximately 17,000 middle managers from 62 different societies. The middle managers worked at one of 825 organizations from one of three industries: financial services, food processing, and telecommunications. In addition to these questionnaire responses, information about culture and leadership was also collected using focus group meetings, media analyses, unobtrusive measures, and archival data.

The conceptual model driving GLOBE is shown in Figure 1.

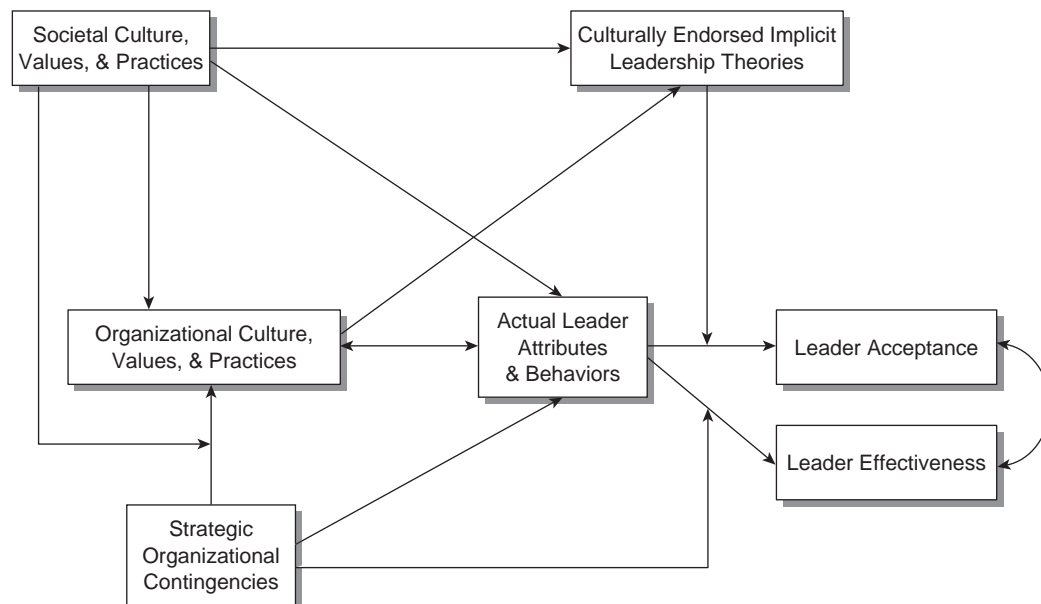

Figure 1 Conceptual Basis for the GLOBE Project

SOURCE: Adapted from House, R. J., Hanges, P. J., Javidan, M., Dorfman, P. W., & Gupta, V. (2004). *Culture, leadership, and organizations: The GLOBE study of 62 societies*, p. 18. Thousand Oaks, CA: Sage. Reproduced with permission.

This model was developed by drawing on implicit leadership theory, value and belief theory of culture, implicit motivation theory, and structural contingency theory of organizational form and effectiveness. The central premise of this integrated model is that the attributes and entities that differentiate cultures from one another are predictive of organizational practices and leader attributes most frequently enacted and seen as effective in those cultures.

The first phase of the project focused on scale development. A total of nine societal culture dimensions and nine organizational culture dimensions were identified from the previous literature. In the GLOBE study, culture was defined as the shared motives, values, beliefs, identities, and interpretations or meanings of significant events that result from common experiences of members of collectives and are transmitted across generations. The nine dimensions of organizational and societal culture were as follows:

1. **Uncertainty Avoidance:** the extent to which members of an organization or society strive to reduce ambiguity by relying on established social norms, rituals, and bureaucratic practices
2. **Power Distance:** the degree to which members of an organization or society expect and agree that power should be stratified and concentrated at higher levels of an organization or government
3. **Institutional Collectivism (Collectivism I):** the degree to which organizational and societal institutional practices encourage and reward collective distribution of resources and collective action
4. **In-group Collectivism (Collectivism II):** the strength of ties within small groups like family and circle of close friends, and the organizations in which they are employed
5. **Gender Egalitarianism:** the degree to which an organization or a society minimizes gender role differences while promoting gender equity and equality
6. **Assertiveness:** the degree to which individuals in organizations or societies are assertive, confrontational, and aggressive in social relationships
7. **Future Orientation:** the degree to which individuals in organizations or societies engage in future-oriented behaviors such as planning, investing in the future, and delaying individual or collective gratification
8. **Performance Orientation:** the degree to which organizations or societies encourage and reward

group members for performance improvement and excellence

9. **Humane Orientation:** the degree to which organizations or societies encourage and reward individuals for being fair, altruistic, friendly, generous, caring, and kind to others

For each culture dimension, separate scales assessing organizational culture and societal culture were developed. Further, for both the organizational and societal culture scales, separate items measuring current cultural practices (*as is*) and cultural values (*should be*) were developed. Thus 36 different culture scales were used in this study (i.e., nine organizational cultural practices scales, nine organizational cultural values scales, nine societal cultural practices scales, nine societal cultural values scales).

Leadership was defined as the ability to influence, motivate, and enable others to contribute toward the success of their organization. Respondents rated 112 different leadership attributes on the extent to which each attribute inhibits or facilitates outstanding leadership. These items were combined into 21 primary leadership scales which were summarized into six global dimensions. The global leadership dimensions are as follows:

1. **Charismatic/Value-Based Leadership.** Leader inspires, motivates, and expects high-performance outcomes from others based on firmly held core values.
2. **Team Oriented Leadership.** Leader emphasizes team building and implementing a common purpose or goal among team members.
3. **Participative Leadership.** Leader involves others in decision making and decision implementation.
4. **Humane Oriented Leadership.** Leader is supportive, considerate, compassionate, and generous.
5. **Autonomous Leadership.** Leader is independent and individualistic.
6. **Self-Protective Leadership.** Leader focuses on ensuring the safety and security of the leader.

The GLOBE leadership scales were developed to measure the implicit leadership beliefs shared by individuals in a culture. Thus these scales are called culturally endorsed implicit leadership theory (CLT) dimensions.

The second phase of GLOBE focused on testing a portion of the integrated model. In particular, the

relationships between societal culture, organizational culture, and the CLT leadership dimensions were tested. The following results were obtained:

- Some leadership attributes were universally endorsed. For example, being trustworthy, planful, dynamic, and communicative are examples of attributes universally rated as facilitating outstanding leadership.
- Some leadership attributes were universally rejected. For example, being asocial, irritable, egocentric, and dictatorial are examples of attributes universally rated as inhibiting outstanding leadership.
- Although some leadership attributes were universally endorsed or rejected, the majority of the attributes were culturally contingent. Overall, both organizational culture and societal culture were significantly related to the CLT leadership dimensions. Further, the cultural value scales predicted the CLT leadership dimensions better than the cultural practices scales. More specifically,
 - Performance orientation cultural values were positively associated with charismatic and value-based, team-oriented, participative, humane-oriented, and autonomous leadership and negatively associated with self-protective leadership.
 - Uncertainty avoidance cultural values were positively associated with self-protective, team-oriented, and humane-oriented leadership and negatively associated with participative leadership.
 - Future orientation cultural values were positively associated with humane-oriented, team-oriented, and charismatic and value-based leadership.
 - Power distance cultural values were positively associated with self-protective leadership and negatively associated with charismatic and value-based and participative leadership.
 - In-group collectivism cultural values were positively associated with charismatic and value-based and team-oriented leadership and negatively associated with self-protective leadership.
 - Institutional collectivism cultural values were negatively associated with autonomous leadership.

This phase of GLOBE also tested whether organizational practices were influenced by the broader societal culture. Consistent with the integrative model, organizational practices were found to be related to societal cultural values. However, the magnitude of this relationship was moderated by industry type. In particular, the practices of food services organizations were the most influenced, whereas the practices of financial organizations were the least influenced by the broader societal culture.

Data analyses on the third phase of the GLOBE project are currently being conducted. This phase was designed to test the contingency hypothesis between the culturally endorsed implicit leadership dimensions and actual leader behavior on leader acceptance and organizational effectiveness. The phase three data came from 20 different countries and consist of behavioral ratings of approximately 40 CEOs from each country. A fourth GLOBE phase is currently in planning.

To date, more than 100 articles, book chapters, and academic presentations have been authored describing aspects of the GLOBE project. The first book has been published, which describes the nature of the project, research strategies, and major findings (including House, Hanges, Javidan, Dorfman, & Gupta, 2004). Another book covering the more qualitative findings by Jagdeep Chokkar, F. C. Brodbeck, and House is expected to be published soon.

GLOBALIZATION

Globalization is the most significant change taking place in today's work environment. It connotes the economic interdependence among countries that develops through cross-national flows of goods and services, capital, know-how, and people. This entry covers mainly the organizational and human aspects of globalization.

Globalization has come into common use since the 1980s, reflecting technological advances and electronic communication that have made it easier to create economic interdependence across countries. Globalization is not just a recent phenomenon. But today commerce and financial services are far more developed and deeply integrated than they were in the past. The most striking aspect of this has been the integration of financial markets made possible by modern electronic communication.

Twenty-five years ago no one talked of *world economy*; the prevalent term was *international trade*, consisting of international trade and foreign investment. But today it has taken the form of a global economy, consisting of flows of information, technology, money, and people, and conducted via government organizations such as NAFTA (the North American Free Trade Agreement) and the European Community; global organizations, such as the International Standard Bureau (ISO) and the International Monetary Fund (IMF); and business corporations, such as multinational companies (MNCs) and cross-border alliances, mergers, and acquisitions. These interrelationships have enhanced participation in the world economy and have become the key to domestic economic growth and prosperity.

MYTHS ABOUT GLOBALIZATION

Global connotes a holistic, integrative strategy. There are some myths about globalization that need to be avoided:

- Globalization is simply a presence in other countries, without any connection between the activities across countries.
- Global strategy means doing things the same way everywhere.
- Globalizing means becoming a stateless organization with no national or community ties.
- Globalization requires abandoning country values.
- There is no need for integration when acquiring or merging with foreign companies.
- A global strategy must involve sales or operations in another country.

In fact, globalization is not about the preceding list. Rather, it is about global integration, and not about internalization.

GLOBAL ORGANIZATIONS

Multinational companies are the dominant players in the global business environment. Some researchers consider MNCs to be the most important institutions of modern societies, because they are more than just businesses. These companies shoulder a huge responsibility for generating wealth by continuously improving their productivity and competitiveness; and their responsibility for defining, creating, and distributing values makes these corporations one of society's principal agents of social change. Members of these organizations, although coming from different cultural backgrounds, have to share common goals and meanings and coordinate their activities to gain a competitive advantage for their company in the global market. The shared meaning and understanding of what it means to be a member of a global corporation, which crosses cultural borders, reflects the global corporate culture.

A GLOBAL CORPORATE CULTURE

Although each MNC may have its own unique organizational culture, global corporations share some common characteristics that reflect their being part of the global business environment. Global corporate values facilitate the adaptation of individuals and organizations to the global work environment.

Competition is a key characteristic of the global market. To gain a competitive advantage in the global market, companies must be performance oriented, emphasizing time to market, cost effectiveness, and customer satisfaction, while also being more

innovative. Furthermore, the global business context is characterized by rapid changes and high uncertainty. Therefore, companies must be *flexible and open to accept changes*. Global corporations need to coordinate and mobilize resources within and across geographical borders. Therefore, *high interdependence* is an important characteristic of global corporations. The high diversity of the global workforce increases awareness of cultural variations, and *acceptance of cultural diversity* has become crucial for effective cooperation across cultural borders. A major proportion of the work in the global environment takes place in global multicultural teams, where cultivating *trust* is critical for team accomplishments. In sum, the global corporate values emphasize competitive performance orientation; flexibility, adaptation to changes, and innovation; high coordination and interdependence; acceptance of diversity; and trust and transparency. The level of agreement on these values among corporate members from different countries is an indication for their being global rather than local values.

A distinction can be made between global and local managerial roles. The former are homogeneously shared by managers in different subsidiaries, including strategic planning, innovation enhancement, and adaptation to change, necessary to compete in the global business environment. Yet, local managerial roles are mainly related to social exchange: providing direction to employees and showing employee consideration. Local managerial roles are influenced by cultural values at the national level, such as power distance and individualism versus collectivism.

GLOBAL IDENTITY

Values are represented in the self, and they shape personal and social identity. The representation of global corporate values in the self, and the sense of belongingness to such corporations, lead to the emergence of *a global identity* as a new form of a person's identity. A person may hold multiple identities, reflecting belongingness to multiple groups. Therefore, a *global identity* does not necessarily compete with a *local-national identity*, which is a person's primary identity. Rather, individuals sample the relevant identity depending on the situation.

Global organizations evoke changes in the local work culture. For example, international trade imposes certain demands on local manufacturing organizations, such as meeting the quality standards

of the International Organization for Standardization's ISO-9000. Countries that want to become players in the global market need to adopt quality-oriented values that support the implementation of ISO-9000. Adoption of these values may change the local national and organizational cultures.

GLOBALIZATION AND CONVERGENCE

The question of whether globalization is leading toward a cultural convergence stirs hot debates. A major argument against cultural convergence is that traditionalism and modernity may be unrelated. Strong traditional values, such as group solidarity, interpersonal harmony, paternalism, and familism, can coexist with modern values of individual achievement and competition. However, research evidence such as that produced by Gili Drori, Yong Suk Jang, and J. W. Meyer points to some convergence in some areas. For example, firms trading globally are likely to imitate each other's practices to boost their own performance. Furthermore, international organizations set the normative expectations, and in this way they play a prime role as agents of world society. Finally, education and science are seen as setting the foundation for economic development, standardization of national practices, and institutionalization of environmental policies, leading toward convergence across countries.

GLOBALIZATION—GOOD OR EVIL?

The question of whether globalization is good or evil continues to be debatable. One of its disadvantages is the growing income gap between high- and low-income countries and the increased number of world citizens who live in poverty. There are fierce protests against globalization during the G8 summits. Strong opposition to globalization usually originates from developing countries that have been hurt by the destabilizing effects of globalization, including Central Asia and Eastern Europe, parts of Latin America, Africa, and parts of South Asia. In fact, fewer than 10% of the world's population are fully globalized. But there is also opposition in Western countries, triggered by significant loss of professional jobs as a result of off-shoring to low-wage countries (<http://www.imf.org/external/np/exr/ib/2000/041200.htm#II>).

Yet, on the positive side, as globalization has progressed, the quality of life and life expectancy have

improved significantly in virtually all countries, with the strongest improvement in the developed countries. The indexes of globalization have strengthened over the last two decades with respect to the following: *world trade* increased 10%, and more so in the newly industrialized economies, in Asia; *capital* movements, and in particular, flow of private capital to developing countries, increased significantly; *workers* moving from one country to another increased dramatically, and the foreign born proportion of labor forces around the world increased by approximately 50%; and the *spread of knowledge and technology* is increasing. Knowledge transfer is accelerated via multinational corporations and global alliances, and company Intranets and the free Internet provide access to knowledge of management techniques, as well as professional and technical know-how.

GOAL-SETTING THEORY

An employee's performance is a function of ability as well as motivation. Ability refers to a person's

knowledge and skill. Knowledge and skill alone do not lead to action. Motivation is the choice to exert effort and to persist, drawing on knowledge and skill, until a desired goal is attained. A typology for understanding motivation includes a person's needs, values, goals, affect, and performance.

Needs are physiological as well as psychological. They affect a person's survival and well-being. Hence, they explain why people take action. Examples of an individual's needs are food, sleep, pleasure, and self-esteem. Thus needs explain why certain broad categories of behavior are universal, but they do not take into account individual differences in the actions people take to satisfy their needs. These differences are reflected in a person's values.

Values refer to a broad tendency to prefer certain states of affairs over others, what the person considers good, desirable, or beneficial. Values reflect beliefs about what is important. For example, some people place far greater value on individualism than collectivism, or low power distance in the workplace than high power distance between leaders and workers. Needs affect action through their effect on values, and values affect a person's behavior through their effect on the person's goals. Goals define for the individual or group what constitutes an acceptable level of performance or direction of action. Thus goal setting has a positive effect on increasing a person's interest in a task in that it provides people with a sense of purpose. Goals engage people's values by challenging them to see how well they can do. Engaging values ensures goal commitment.

Edwin A. Locke and Gary P. Latham's goal-setting theory states that goals are the immediate precursors and regulators of much, if not most human behavior. The theory does not imply that a person must always be fully consciously aware of a goal for it to regulate behavior. But it does state that given that there is commitment to a goal, it remains in the periphery of consciousness as a reference point for guiding and giving meaning to subsequent psychological and physiological actions that lead to goal attainment.

Goals have two main attributes: content and intensity. Goal content is the object or result that is sought. It can vary quantitatively in that a person may have few or many goals. People can have short-term proximal goals in addition to a long-term distal goal, and their goals may be easy or difficult. Goals may also vary in specificity from a vague and abstract one, such as *do your best*, to a specific one, such as to decrease

costs by 20% within the next 12 months. Goals may also vary in type from a focus on a performance outcome to learning or discovering a specific number of processes or to those that are behavioral in nature.

Goal intensity refers to the determinants and effects of goal commitment on performance as well as the place of a given goal in a person's goal hierarchy. Goal content and intensity can be related. An intense psychological process might be involved in setting a clear, specific goal rather than a vague goal in a situation where a great deal of information has to be analyzed and integrated before a goal can be clearly formulated. Hence, setting a specific performance goal in this instance would be more intense than adopting a vague goal.

A core finding of more than 1,000 studies on goal setting is that higher goals lead to greater effort and persistence than easy goals, given that the person is committed to attaining them. With regard to affect, higher goals make self-satisfaction more contingent on a higher level of performance than easy goals. Moreover, high goals are usually seen as more instrumental in attaining valued outcomes than easier goals. People typically view their actions that fall short of their desired goal as unsatisfactory. When a person's self-efficacy—namely, task-specific self-confidence—is high, a negative self-evaluation usually leads to subsequent actions to eliminate the source of dissatisfaction, such as finding ways of improving subsequent performance. Action that leads to meeting or exceeding a goal results in positive appraisals. However, if a positive appraisal is followed by anticipation that attaining the same performance level again leads to a neutral or negative self-appraisal, the person is likely to set an even higher goal. In short, goals are the value standard by which people appraise their performance.

A second core finding of goal-setting theory is that goals that are specific and difficult lead to a higher level of performance than vague, abstract goals such as to *do your best*, even though the latter exhortation implies a high level of motivation. This is because the ambiguity inherent in an abstract goal allows people to give themselves the benefit of the doubt in evaluating their performance. Hence, a wide range of performance levels may be interpreted as aligned with the desire to *do one's best*. In contrast, a specific high goal makes explicit what constitutes an acceptable outcome.

These two core findings are seen in a wide spectrum of employees including loggers, factory workers,

production and marketing personnel, engineers, scientists, and college professors. These findings have been obtained in Australia, Canada, the Caribbean, Germany, Israel, Japan, and the United States. The performance characteristics studied include quantity and quality of work, production efficiency, time spent on task, profits, costs, job behavior, performance appraisal ratings, and survey returns. These findings apply to groups in addition to the individual.

Three motivational mechanisms explain how goals affect performance, namely, choice, effort, and persistence. A fourth mechanism is cognitive, namely, the discovery of appropriate strategies. With regard to choice, clear specific goals have two directional effects that are relatively automatic. First, they point a person toward goal-relevant activities and materials, and away from goal-irrelevant ones. Second, they activate stored knowledge and skills that an individual possesses that are perceived as relevant to the task.

Once the choice has been made, goals energize performance by motivating people to exert effort in line with the difficulty or demands of the goal. Holding a person's ability constant, scores of studies have shown that rate of performance is a linear function of goal difficulty. That is, given goal commitment, the higher the goal, the higher the performance.

Persistence is ongoing effort, typically assessed in the form of duration of time spent on an activity. High goals increase the probability that a person will continue to work for a longer period of time than is the case with a vague or easy goal.

These three mechanisms, choice, effort, and persistence, operate automatically once the person commits to a goal. When people have yet to acquire the knowledge or skill necessary to attain a specific high goal, a learning rather than a performance goal should be set. This is especially so on tasks for which minimal prior learning or performance routines exist, where strategies that were once effective suddenly cease to be so. If this is not done, setting a specific high-performance goal can actually lead to lower performance than urging people to do their best. This is because people feel pressure to perform well immediately before taking the time to explore systematically optimal ways to perform the task.

The primary distinction between a performance and a learning goal is framing the instructions. The instructions respectively associated with the two types of goal invoke two different domains, namely, motivation and ability. With a performance goal, as the name

implies, the goal is framed so that the focus is on the result. A search for information to attain the goal is neither mentioned nor implied because ability is a given. Performing effectively requires only the choice to exert effort and persist until the goal is attained. Similarly, with a learning goal, as the name implies, the goal is framed so that people focus on knowledge or skill acquisition—the search for and implementation of effective strategies. Thus a learning goal draws attention away from the end result. The focus instead is on discovering an appropriate process. Learning goals are particularly relevant in fast-changing organizational environments and industries that are prone to abrupt changes, and in which strategies once effective can quickly become obsolete. Relative to performance goals, they increase the probability that appropriate strategies will be discovered for mastering a task. In such instances, commitment to a learning goal has been found to be higher than for a performance goal. This is a result of goal intensity, namely the amount of thought or mental effort that goes into formulating a plan of action required of the former relative to the latter. Research is now needed to study under what conditions learning goals lead to learning, that is, the discovery of appropriate strategies or processes.

Behavioral goals, set based on a systematic job analysis, can obviate the need for a learning goal even though the task is complex for people. Behavioral goals are appropriate in relatively stable environments where the appropriate course of action is already known, and where end result variables are not easily measured for each individual, or the latter are affected by factors beyond the person's ability to control.

Among the ways to foster goal commitment is to have goals assigned by an authority figure, make the goals public, and increase the person's self-efficacy. Assigned goals lead to commitment because listening to the assignment without objection is itself a form of consent, and assigning the goal implies the person is capable of attaining it. This is particularly true when the person who assigns the goal is perceived as supportive and trustworthy. Making a goal public makes attainment an issue of integrity and thus binds a person more strongly to it than committing to it privately. This is because few people want to be subsequently seen by others as failures or hypocrites. Self-efficacy is people's judgment of how well they can execute courses of action required to deal with prospective situations. People with high self-efficacy set and commit to high goals. Obstacles and hurdles to overcome are

viewed as challenges and sources of excitement. People with low self-efficacy view the same obstacles and hurdles as concrete reasons for abandoning a goal.

Goal commitment can also be fostered by monetary incentives. There has been little research to date on optimal ways to design incentive plans to motivate people to try for high goals, and yet not become demotivated by getting close to the goal but not attaining it. Large incentives may also tempt some people to find ways to cheat.

Goal setting is effective regardless of whether the goal is self-set, participatively set, or assigned. Self-set goals are the core of self-management. Participatively set goals on tasks that are straightforward for people have sometimes been found to lead to higher goals than is the case when the goal is assigned by a supervisor. As noted earlier, the higher the goal, the higher the performance. Performance is equally high, as is commitment to the goal, when the assigned goal is as difficult as the one set participatively, the logic or rationale for the assigned goal is provided, and confidence is expressed in the employee's ability to attain it. On tasks that are complex for people, participatively set goals are preferable only to the extent that through discussion they lead to the discovery of better task strategies and an increase in self-efficacy regarding the application of these strategies.

Goals have an anticipatory, feed-forward effect by energizing action at the beginning of a work period. Regardless of the method used for setting a goal, feedback in relation to goal attainment is nevertheless critical. Feedback allows people to adjust their effort, persistence, and strategy with this information. One way to conceive of the relation between goals and feedback is as follows: Feedback tells people what is; goals tell them what is desirable. Feedback involves information; goals involve evaluation. Goals inform people as to what type or level of performance is to be attained so that they can direct and evaluate their actions and efforts accordingly. Feedback allows them to set reasonable goals and to track their performance in relation to their goals, so that adjustments in effort, direction, and strategy can be made as needed. To correct an old but not completely accurate axiom in organizational psychology, That which gets measured in relation to goals is done.

GRAPHOLOGY

Graphology, or handwriting analysis, is sometimes used to assess personality or make inferences about specific attributes such as integrity. The underlying theory is that there are a number of structural characteristics of a person's handwriting that provide reliable indications of personality, including traits such as honesty or loyalty. There are serious questions regarding the validity of assessments provided by this technique; graphology is sometimes classified as a quasi-occult practice, comparable to astrology, palmistry, numerology, and other similar methods. Despite well-founded concerns about the validity of graphological assessments, this method is widely used, especially in Israel and France. In the United States several thousand employers are thought to use graphology in preemployment screening.

It is important to distinguish graphology from the practice of forensic graphoanalysis. Graphoanalysis is

a method for authenticating documents such as letters and signatures and is widely used in criminal investigations and in civil procedures including contested wills. Graphoanalysts do not attempt to draw inferences about the person based on handwriting; graphologists claim to be able to make such inferences.

THE GRAPHOLOGISTS' METHOD

Graphology involves an examination of a number of specific structural characteristics of a handwriting sample, such as letter shapes and sizes, which are used to make inferences about the writer. For example, in some systems of graphological analysis, the degree of slope in a person's letters is thought to indicate the extent to which a person is introverted versus extroverted. Computerized systems for handwriting analysis exist, but most graphological analyses are still done by individual graphologists. Graphologists typically insist that the handwriting sample for analysis must be spontaneous and that handwriting samples involving copying text from a book or writing a passage from memory do not yield a valid reading. The writing sample requested by a graphologist is often a brief autobiographical sketch or some other sort of self-description.

Graphologists claim that neither the content nor the quality of the writing sample, such as fluency and clarity of expression, influence their assessments and that their evaluations are the result of close examination of the features of letters, words, and lines in the sample. There are several reasons to believe that this claim is false and that even if graphologists try to ignore the content of the writing sample, their assessments are nevertheless strongly influenced by that content. First, several studies have shown that when the same biographical passages are examined by graphologists and nongraphologists, their assessments of individual examinees tend to agree, and graphologists are no more valid in their assessments than nongraphologists. Because nongraphologists presumably do not attend in a systematic way to the graphological features of the writing, but rather to the content of the stories, their ability to make assessments that are similar to and every bit as good as those made by professional graphologists strongly suggests that both groups are attending to the same material—specifically, the content of the writing samples. Indeed, studies by Gerson Ben-Shakhar and his colleagues have shown that predictions based solely on the content of the writing

sample are more valid than those obtained from professional graphologists. Second, when the content of passages is not biographical in nature (e.g., meaningless text or text copied from some standard source), graphologists seldom make valid predictions. If their predictions depended solely on the structural features of letters, the content of the passages should not make a difference.

VALIDITY OF GRAPHOLOGICAL ANALYSIS

In evaluating graphology, there are two separate questions that might be asked. First, how valid and reliable are the general predictions produced by a graphological analysis? For example, if graphology is used in personnel selection, we might ask the graphologist to predict who is more or less likely to perform well on the job. Second, how accurate are the specific assessments of particular personality traits? If graphology is used to measure specific traits, such as integrity, we might ask whether this method provides valid measures of that trait.

There is evidence that graphologists can make somewhat valid predictions of a job applicant's overall performance, but it is also clear that nongraphologists who examine the same material make equally valid predictions. This research suggests that there is little to be gained from attending to the purely graphological aspects of the writing sample.

The available evidence also casts doubt on graphologists' ability to make even the most general assessments of individuals, or at least to do a better job than nongraphologists given the same materials. It is notable that graphologists refuse to predict some easily verifiable characteristics of writers, such as their gender, something untrained individuals can do with considerable accuracy. There is no reason to believe that graphological assessments of specific characteristics such as honesty and integrity are accurate or valid.

ACCOUNTING FOR THE CONTINUING APPEAL OF GRAPHOLOGY

Numerous studies of graphology show that assessments of personality made on the basis of examination of the structural characteristics of handwriting samples are neither valid nor valuable. The underlying theory—that specific personality characteristics are reliably translated into specific characteristics of a person's handwriting such as the size of letters, the

degree of slant, or other common graphological signs—is simply wrong. Given its questionable status, how can someone account for the continuing popularity of graphology?

There are several potential explanations for the continuing popularity of graphology. First, the idea that handwriting reveals character is ancient and can be traced at least as far back as the Roman Empire, and the assumption that graphology *should* work has long been common in Western civilization. Second, proponents of this method claim that graphology provides what virtually every manager wants—a window into the minds of the employees. Third, it is a potentially unobtrusive method. For example, it is common to ask job applicants to provide a brief biographical statement, which can easily be subjected to graphological analysis.

Although it remains an important part of many selection systems, there is no justification for using graphology to make important decisions about individuals.

GRAVITATIONAL HYPOTHESIS

The gravitational hypothesis is a theory that suggests that workers will gravitate, or move, to jobs that match their cognitive ability. Cognitive ability,

generally speaking, is a person's cognitive capacity or general mental capability that determines how quickly that person can process and understand concepts and ideas. It is believed to be stable once a person reaches adulthood. According to the gravitational hypothesis, one driver of workers' movement across jobs is their general cognitive ability such that high-ability workers gravitate toward jobs with high cognitive demands and low-ability workers gravitate toward jobs with low cognitive demands. Said another way, workers gravitate to work that they can adequately perform.

Clearly, there are many potential drivers of worker mobility across jobs, but this theory focuses on general cognitive ability in particular. Because cognitive ability is unchanging, workers must move to jobs where they can achieve the best match between their abilities and the cognitive demands of the job. Thus cognitive ability, mobility, and person–job match are all dimensions of the theory.

COGNITIVE ABILITY, MOBILITY, AND PERSON–JOB MATCH

Although the context within which workers are moving, the labor market or the market where workers find work and organizations find employees, was a focus of mobility researchers for years, the gravitational hypothesis placed a lens specifically on workers' characteristics. The state of the labor market, such as whether jobs were plentiful or not, was a key contextual factor for the frequency and type of worker mobility. Frequency is the rate or speed with which workers move across jobs in the labor market. Type of mobility is the direction of movement: upward, downward, or lateral. In some research, type of mobility is determined by the change in the salary of the work. An upward move denotes a move to a job with a higher salary than the job held previously, a downward move denotes a move to a job with a lower salary than the job held previously, and a lateral move denotes a move to a job with the same salary as that held previously. In a labor market where jobs are plentiful, workers are expected to move more frequently and have greater opportunities to move to work with higher wages. The worker's characteristics played a decidedly *backseat* role in the mobility process.

The gravitational hypothesis suggested that worker characteristics, specifically general cognitive ability, should play a more central role in understanding the mobility of workers in the labor market. Moreover,

type of mobility should relate directly to whether or not workers gravitate to work that matches their cognitive ability level. Upward moves suggest a move to work of greater cognitive demands than the work held previously. Downward moves would suggest a move to work of lesser cognitive demands and lateral moves would suggest a move to work of the same cognitive demands compared with the job held previously. Although higher salaries were always preferred over lower ones, this conceptualization of mobility type requires a more complicated calculus to determine whether one move would be preferred to another. Both worker cognitive ability and job cognitive demands need to be considered and the match between them evaluated. Sometimes improving the match requires a move down in job demands and sometimes it requires a move up.

Sorting workers both up and down in terms of cognitive demands runs counter to many views of mobility as generally upward. Further, there are some theories, such as the *Peter Principle*, that suggest that workers will be promoted to the point above their competencies. The gravitational hypothesis argues that when workers find themselves in work beyond their capabilities, they are more likely to gravitate to work with lower cognitive demands than to either stay in the job or move further upward. That is, overemployment, work beyond worker capability, is more likely to lead to a shift downward in an effort to create greater parity between worker capability and job demands. Likewise, underemployment, work that is beneath worker capability, is believed to more likely lead to a shift upward to work that has higher cognitive demands. Whether the worker or the organization is the catalyst for change, such as if the worker quits or is fired, is not differentiated in the theory. Regardless of the direction of movement or the catalyst for the change (e.g., worker or organization), moves that improve the match between workers' cognitive ability and the work's cognitive demands are preferred according to this theory.

Thus the gravitational hypothesis suggests a dynamic model of person–job match. Person–job match, the match between person characteristics or desires and the demands or characteristics of the job, can be measured on a variety of dimensions. If a person desires a flexible schedule, finding a job that provides flexibility is considered a good match on this dimension. If a person has a preference for a certain type of workplace culture, finding an organization

with such a culture would be a good match on this dimension. The gravitational hypothesis focuses on one dimension of person–job match, the match between worker cognitive ability and work cognitive demands. It is important to note that a person may be seeking match on a variety of these dimensions simultaneously, making fully explicating the matching process difficult. Indeed, matching is a process, one that the gravitation hypothesis acknowledges directly. Gravitation is about movement or change, and the gravitational hypothesis is about movement that leads to improved match between worker ability and the cognitive demands of the work.

Originally, the gravitational hypothesis was developed by job analysis researchers who observed that workers with long job tenures were more likely to have the capability to meet the demands of the work, suggesting that match encouraged stability. Workers still seeking match were more likely to leave jobs and organizations. Indeed, research has found a common outcome of mismatch between workers and their work turnover. Other outcomes of mismatch are low satisfaction and performance. Thus achieving match between workers and their jobs is beneficial to both organizations and workers. A matched employee is more likely to be satisfied, to perform better, and to have long job tenure. The probability of match may be increased through careful recruiting and selection practices that allow both applicants and prospective employers the opportunity to share information that allows for assessment of match quality.

GROUP COHESIVENESS

In trying to understand what makes work groups and teams effective, an important question for theory and practice is what keeps a group together, or what leads the members of a group to stay committed to the group? The term *group cohesiveness* (or *cohesion*) was coined by Leon Festinger and colleagues to refer to the social glue that binds group members together. Thus group cohesiveness refers to the resultant of all the forces acting on members to remain in the group or simply to group members' attraction to the group.

The concept of group cohesiveness has a wide appeal in research in applied psychology in such diverse areas as organizational behavior, social psychology, military psychology, sport psychology, educational psychology, and counseling. Much of this interest is inspired by the widely shared recognition that keeping groups together is important to the successful functioning of systems relying on group work. Aside from a concern with what leads group members to remain with a group, the interest in group cohesiveness is also inspired by the assumption that more cohesive groups function better, at least in part because members of more cohesive groups presumably are more willing to exert themselves on behalf of the group. Evidence for this proposition is mixed, however. To address this issue, Brian Mullen and Carolyn Copper (1994) integrated the results of many studies on the relationship between group cohesiveness and group performance. Their conclusion is that group cohesiveness may better be viewed as a construct with different aspect, and that the aspect of cohesiveness that has to do with group members' commitment to task performance and goal achievement is the most important in predicting group performance. Complementing these findings, more recent evidence suggests that whether group cohesiveness is conducive to group performance is contingent on the extent to which the group embraces high performance goals and norms. If not, high cohesiveness may in fact be associated with lower performance.

THE DIMENSIONALITY OF GROUP COHESIVENESS

Group cohesiveness has always been at least implicitly associated with a greater willingness of group members to exert themselves on behalf of the group

and therefore with increased group productivity and performance. Some issues complicate our understanding of the concept of group cohesiveness and its consequences, however.

A first issue is the measurement of group cohesiveness. The concept of group cohesiveness refers to the forces that bind individuals to the group or the attraction of group members to the group. The most common way to measure group cohesiveness, however, is to measure individual group members' attraction to other group members (i.e., rather than to the group). Interpersonal attraction may be an aspect of group cohesiveness, but it is not the only aspect of group cohesiveness and might not be the most important one. Indeed, the definition of group cohesiveness suggests that attraction to the group as a whole (i.e., rather than to individual members) is more central to the concept. Many studies of group cohesiveness may thus fail to capture important aspects of the concept.

A second issue follows from the first. Many researchers and practitioners alike tend to think of group cohesiveness as a one-dimensional construct, that is, a concept reflected in a single characteristic of the group. Theoretical considerations as well as a review of measurement practices suggest, however, that it may make more sense to think of group cohesiveness as a multidimensional construct—in other words, as a concept reflecting different aspects of the group. Interpersonal attraction between group members may be one of these aspects but not the only one. A second important aspect of group cohesiveness is cohesiveness as it flows from attraction to the group's goals and mission and commitment to the group's task. That is, group members may be attracted to the group because they value what the group is trying to achieve. A third aspect that may be important in the group's attraction to its members is the value to group members of being a member in the group, *per se*. Part of a group's attractiveness may flow from the group's prestige or from other factors that may render members proud of their membership in the group. As Mullen and Copper's (1994) review of the literature shows, these three aspects are represented in different studies of group cohesiveness, and the relationship between these different aspects is small enough to see them as separate aspects of group cohesiveness. Moreover, these different aspects are differently related to group performance.

GROUP COHESIVENESS AND GROUP PERFORMANCE

Mullen and Copper (1994) conducted a meta-analysis—a quantitative summary of the results of a number of empirical studies—of research on the relationship between group cohesiveness and group performance. Following from their review of the literature, they distinguished between interpersonal attraction, task commitment, and group pride as different parts of group cohesiveness. What they found was that task commitment was most strongly and most consistently (positively) related to group performance. In particular, the contribution of interpersonal attraction between group members turned out to be very modest at best—and could indeed even be negative. Group members' attraction to the group's goals and task thus seems to be the part of commitment that is most important in predicting group performance.

On the practical side, these findings suggest that attempts to boost work group performance by fostering cohesion will be relatively ineffective if they concentrate on building interpersonal attraction between group members, such as by organizing social events for the team, or by boosting group pride. Rather, such attempts are better focused on increasing group members' commitment to the group task and group goals; for example, this effect is often attributed to charismatic and transformational leadership.

An important caveat in this respect is that short-term group performance may be only one aspect of viable group functioning. For other aspects of group functioning, and perhaps also in the longer run, other aspects of group cohesiveness may play a more important role than suggested by Mullen and Copper's (1994) focus on relatively short-term task performance. There is, for example, research suggesting that the more social aspects of group cohesiveness such as interpersonal attraction may play a role in longer-term group viability. Arguably, although interpersonal attraction and group pride may not contribute much to group performance directly, they may be important in retaining valued members of the group, and thus for group performance in the longer run. We should be cautious in concluding from a narrow focus on proximal task performance that only certain aspects of group cohesiveness are important for effective group functioning.

It is important to realize, when it comes to the relationship between group cohesiveness and group

performance, that group performance may also affect group cohesiveness. Group cohesiveness may lead to group performance, but group performance may also lead to group cohesiveness. When a group performs well rather than poorly, this may render the group more attractive. Indeed, Mullen and Copper's (1994) analysis suggests that the effect of group performance on group cohesiveness might be twice as strong as the effect of group cohesiveness on group performance. This is not to say that group cohesiveness does not matter in engendering high performance, but it does caution research and practice in group cohesion and performance that observed correlations between cohesion and performance may reflect the influence of performance on cohesion more than the influence of cohesion on performance.

Another important issue in the relationship between group cohesiveness and group performance is that it is probably better to think of group cohesiveness as motivating a willingness to exert oneself on behalf of the group and not necessarily as motivating high group performance. That is, members of highly cohesive groups may be attracted and committed to their group and motivated to exert themselves in pursuit of what they perceive to be the group's interest, but they need not perceive high performance as being central to the group's interest. This is nicely illustrated in a study by Philip M. Podsakoff, Scott B. MacKenzie, and Michael Ahearne (1997). These researchers studied the relationship between the cohesiveness of work teams in a paper mill and team productivity. Specifically, they looked at the influence of the teams' commitment to organizational performance goals on the relationship between group cohesiveness and group productivity. What they found was that higher group cohesiveness was only associated with higher productivity when commitment to organizational performance goals was high. When commitment to performance goals was lower, group cohesiveness even tended to be negatively related to productivity. Other research obtained similar findings for the role of group norms—only when groups accepted high performance norms did cohesion positively predict performance. These findings suggest that organizations may thus only expect positive effects of high-group cohesiveness when groups embrace organizational performance goals and norms.

GROUP DECISION-MAKING QUALITY AND PERFORMANCE

The need for broad representation and a wide range of expertise often necessitates the use of groups to make important decisions. Indeed, group decision making is evident in product development teams, corporate boards, juries, and emergency medical teams. Group decision making involves the process of reaching agreement on a given set of alternatives among multiple individuals. Through interaction and discussion, individual positions or preferences are transformed into a consensus choice. Research in this literature has mostly focused on small groups, typically with a size of 4 to 7 members but reaching up to 12 members in jury decision research. What distinguishes group from individual decision making is the need to reconcile various positions and preferences into a collective decision. A common assumption is that groups can make higher-quality decisions and better detect errors than individuals acting alone. However, research has shown that group outcomes are not always superior to

those of individuals. Instead, the factors contributing to group decision-making success or failure are numerous, complex, and situationally contingent.

ADVANTAGES AND DISADVANTAGES OF GROUP DECISION MAKING

The belief that *several heads are better than one* underlies the reliance on groups to make important decisions in business, military, medical, and governmental contexts. Groups, as opposed to individuals, represent a diversity of perspectives, areas of expertise, and values. In addition, groups can distribute the responsibility for consequential decisions across many members. Furthermore, people may reject decisions made by a single authority, whereas collective decision making may increase the acceptability and ease of implementation of decisions.

Despite these advantages, however, group decision making also suffers from significant limitations. For example, groups often take longer to arrive at a choice than individuals. In addition, although group decision making is expected to lead to superior performance when no single member has all the necessary information to identify a correct solution, extensive laboratory research has revealed that groups tend to discuss information that is shared by all members as opposed to pooling the unique information held by individual members. Therefore, the potential for different individuals to bring independent, unshared, and valid information to the group is never realized, which contributes to incorrect group solutions. Nevertheless, information sharing has been found to improve over time, and leadership as well as training can improve the dissemination of knowledge in teams.

Although groups are often expected to neutralize individual biases in decision making, they have been found to fall prey to some of the same errors as individuals. The question of whether groups are any less subject to judgmental biases than individuals depends on a variety of factors, including group size and the type and magnitude of bias, as well as group processes.

Some research has found that groups exaggerate the biases of individual group members. Specifically, group polarization refers to the finding that groups are more extreme than the mean of individuals. For example, if members adopt a cautious or risky viewpoint prior to group discussion, they tend to have an even

more cautious or risky viewpoint after deciding together as a group.

Another disadvantage to group decision making is the potential for groupthink, which has received much emphasis in the literature. Groupthink occurs when the premature striving for agreement among members produces faulty decisions. To combat these limitations and improve group decision making, many techniques have been proposed to establish new patterns of social interaction, change the sequence of steps in information processing, or develop specific procedures for task accomplishment.

TYPES AND STAGES OF GROUP DECISION MAKING

There are two major categories of group decision making. One type involves members discussing decision alternatives and combining their preferences to arrive at a collective solution. A second type is called hierarchical decision making because a team leader asks for input from group members, but that team leader makes the final decision. For example, a department chair may be advised and informed by various faculty committees but determines the final choice alone.

Similar stages have been proposed for both individual- and group-level decision making, namely issue identification, alternative generation, evaluation, and choice. During issue identification, relevant information is acquired and issues are defined and interpreted. In the alternative generation stage, decision criteria are chosen and alternatives are proposed. Finally, alternatives are evaluated and a decision is selected. Some models of group decision making also include an implementation phase in which actions are coordinated and monitored.

GROUP DECISION-MAKING EFFECTIVENESS

Two broad categories that can be used to assess group decision-making effectiveness are decision outcomes and affective outcomes. Decision outcomes include acceptance of the decision by those affected by it, whether the decision stands or is subsequently overturned, and how successfully it is implemented. In addition, decision accuracy or quality has been researched extensively. Affective outcomes include satisfaction with the final decision, fairness of the processes used to arrive at consensus, and whether

members would like to continue working together. Both short- and long-term outcomes should be considered in the assessment of decision-making effectiveness.

FACTORS CONTRIBUTING TO GROUP DECISION-MAKING EFFECTIVENESS

Existing models recognize that effective and ineffective group decision making is determined by a wide range of factors. A sampling of the variables that have been investigated in this literature follows.

Decision Rule

Group members must implicitly or explicitly select and implement decision rules to determine how individual preferences will be combined to produce a collective decision. Majority rule and unanimity are the most common methods of social choice. In a simple majority, 51% or more of group members must agree, whereas unanimity requires that all members agree. Group decisions often are more difficult to reach and require more discussion under unanimity rule than under majority rule. In contrast, majority rule is more efficient and less time-consuming, and it prevents impasses more than does unanimity. However, majority rule may not be the preferred decision rule in groups with conflicting viewpoints, because it cannot always resolve diverse preferences in a way that contributes to effective group functioning. Unanimity drives groups toward more systematic processing of information because attention must be paid to all members' perspectives.

Social Decision-Making Schemes

Related to decision rules, prediscussion preferences of group members can be related to group decisions through simple functions or rules, termed *social decision schemes*. Examples include *majority rule* (group decision is favored by more than half of group members), *truth wins* (one correct member is necessary and sufficient for a correct group response), and *truth supported* (two correct members are necessary and sufficient for a correct group response).

Social decision schemes are probabilistic models, and their fit can be assessed through statistical tests. A reoccurring finding in this research is that groups tend to decide for an alternative that is supported by the

majority of members, despite the fact that it may not be the correct solution. However, a major value of this research has been to trace the ways in which the best fitting or most predictive social decision scheme varies with the decision environment and type of task. For example, truth wins tends to be the best fitting social decision scheme for intellectual tasks where a demonstrably correct solution exists. In contrast, truth supported tends to be the best fitting combination process for general world knowledge and vocabulary. Furthermore, the best fitting social decision scheme for juries is a two-thirds majority.

Minority Influence

In the absence of dissenters, convergent thinking strategies are used, which involve a narrow focus with little cognitive effort. However, the presence of dissenting minorities causes group members to think more divergently; that is, their thoughts cover a wider range of perspectives. Majority members seek understanding of the minority position to better reject it, and the tension produced by conflicting perspectives produces divergent thinking. As a result, groups with dissenting minorities have been found to produce more innovative ideas than groups without dissenting minorities.

Conflict

In the past 15 years, it has been recognized that conflict can be a functional and stimulating mechanism in groups as opposed to a stressful and disruptive event. As a result, some decision-making interventions such as devil's advocacy encourage group members to challenge each other's ideas to foster debate and critical analysis. Some research suggests that these techniques do yield better group decisions. However, not all conflict is beneficial. Although task-related conflict fosters a deeper discussion of the issues by fostering disagreement about ideas, relationship conflict results in animosity, anger, and tension between group members.

GROUP DECISION MAKING IN ORGANIZATIONS

The majority of research in group decision making has been conducted by social psychologists who mostly use laboratory experiments and ad hoc groups. Therefore, it is not clear if all results can be generalized

to groups in organizations, in which members have a history and stay together for extended periods of time. However, over the past decade, organizational psychologists have gotten more involved in group decision-making research to overcome the artificiality of laboratory work. Recent group decision-making models include more *real world* variables such as political factors, stress from external threats, member history, and the likelihood of future group interactions. Therefore, it is expected that new insights will be gained concerning the effects of organizational factors on group decision making in the next few years.

GROUP DECISION-MAKING TECHNIQUES

A group decision-making technique is a strategy for structuring group members' interactions to enhance the quality of a collective decision. It is a set of rules or procedures that specify the process members should follow when contributing to a decision pertaining to their group.

An effective group decision is characterized by a full use of members' resources, an efficient use of

time, and a high-quality outcome. A number of group process deficiencies or roadblocks can hinder one or more aspects of effectiveness. For example, group members may withhold critical input because they do not want to interrupt another person (i.e., production blocking), feel apprehensive about being evaluated by other group members, have been interrupted by another person such as a domineering teammate, or be prone to social loafing wherein individual effort decreases as group size increases. Furthermore, members may ignore teammates' input because they are unwilling to consider alternative viewpoints or because they are distracted as they closely monitor the conversational flow for opportunities to state their own ideas. Collectively, these and other barriers can cause groups to evaluate solutions before all members have provided input or exhausted their supply of ideas and suggestions.

A group decision-making technique is designed to enhance effectiveness by diminishing barriers and roadblocks such as those described earlier. Four of the most commonly cited group decision-making techniques are brainstorming, the nominal group technique, the Delphi technique, and the stepladder technique. These techniques vary in the manner in which they structure group problem solving. They also differ according to the particular process deficiencies they aim to minimize.

BRAINSTORMING

Groups often make ineffective decisions because they either fail to sample an adequate domain of alternative solutions or do a poor job of evaluating and selecting among the alternatives considered. Brainstorming is a group decision-making technique designed to address the first of these two issues by increasing the range of ideas and solutions available for the group to explore. Brainstorming groups meet specifically to generate alternatives. They are instructed to produce as many ideas as possible. Brainstorming does not provide a problem solution or decision itself. Instead, it produces a list of alternatives that will later be considered, discussed, and evaluated when it is time to reach a final decision.

The ground rules include the following:

- **Suspend judgment:** Evaluation and criticism of ideas during brainstorming should be avoided.
- **Permit freewheeling:** Group members should offer any ideas they have, no matter how impractical. Wild

ideas, even those considered too risky or impractical to implement, are expected.

- **Emphasize quantity, not quality:** Quantity should be stressed, not quality. All ideas should be expressed. None should be screened out. This is intended to encourage people to move beyond their favorite ideas, thereby producing a more complete range of alternatives.
- **Encourage pooled creativity and synergy:** Members should build on others' ideas when possible. People should feel free to make combinations from others' suggestions.
- **Ignore seniority:** During brainstorming, group members should behave as if everyone were the same rank. Political motivations should be set aside. Brainstorming should be characterized by a relaxed, cooperative, uninhibited, congenial, egalitarian atmosphere.
- **Ensure all voices are heard:** It is important to ensure that all members participate in the brainstorming session, no matter how reluctant they are to contribute.
- **Record all ideas:** Every idea produced during the brainstorming session should be recorded for later discussion.

The purpose of brainstorming is to prompt divergent thinking, produce many different ideas in a short period of time, and encourage full participation among all group members. It is designed to minimize stifling ideas by domineering members, interpersonal conflicts, stereotypes of others' expertise or intelligence, habitual patterns of silence, and evaluation apprehension.

Brainstorming can be implemented in one of several ways. In one version of brainstorming, group members convene and randomly verbalize their ideas, which are captured by a tape recorder or a facilitator who writes them on a flip chart. Research has shown this strategy to be less effective than simply having people generate ideas on their own, independent of the group. Social anxiety and evaluation apprehension prevent some members from blurting out their ideas in a group. Additionally, groups experience production blocking, which is a norm where only one member speaks at a time. During production blocking, ideas that might have emerged are forgotten or censored while a member awaits the opportunity to speak.

Electronic brainstorming is an alternative that is more effective than the face-to-face procedure described earlier. During electronic brainstorming, group members enter ideas into the computer, either

anonymously or not, and each member is able to see the ideas shared by others. The production-blocking problem described previously is all but eliminated because multiple people can enter ideas simultaneously. Research has shown that this form of brainstorming is more effective than its face-to-face alternative, with electronic brainstorming groups performing as well as or better than people generating ideas on their own.

THE NOMINAL GROUP TECHNIQUE

The nominal group technique facilitates both the generation and evaluation of ideas. Unlike brainstorming, this strategy results in a final group decision. The nominal group technique typically involves the following steps:

- **Write ideas in private:** After the problem at hand is understood, members silently generate their ideas in writing. No discussion among members is permitted at this point.
- **Take turns reporting ideas:** Members take turns reporting their ideas to the group, one at a time, while a facilitator records them on a flip chart or blackboard. Again, no group discussion occurs during this step. This round-robin listing continues until each member has no more ideas to share.
- **Discuss ideas:** Next, group members discuss the ideas that have been recorded. The main purpose of this discussion is to clarify, criticize, or defend the stated ideas.
- **Vote on ideas:** Each member privately and anonymously prioritizes the ideas. This nominal voting step may involve a rank-ordering system, a weighted voting procedure, or some similar mechanism for reporting preferences.
- **Calculate the group decision:** The group decision is calculated mathematically, based on the vote described earlier. The final decision is the pooled outcome of the individual votes.
- **Repeat if necessary:** Some variations of the nominal group technique allow the generation–discussion–vote cycle described previously to be repeated until an appropriate decision is reached.

The nominal group technique was developed to overcome a number of decision-making roadblocks. The highly structured and task-focused nature of this strategy is thought to encourage the efficient use of time by reducing the propensity for nonproductive digressions and hostile arguments. The nominal

group technique likely decreases evaluation apprehension by having members write their ideas privately and by separating the brainstorming phase from the later idea evaluation phase. Requiring group members to brainstorm their ideas independently and in writing also facilitates idea generation by reducing production blocking. Taking turns reporting written ideas encourages balanced participation and discourages domineering or high-status members from blocking others' input. Members may also experience an increased sense of accountability and a decreased propensity for social loafing, because members are required to publicly state their written ideas. Finally, the round-robin listing of ideas prevents groups from prematurely evaluating solutions before all members have provided input or exhausted their supply of suggestions.

Despite its positive features, some have argued that the structured nature of the nominal group technique may limit creativity. Research has shown that groups organized according to this method express less decision satisfaction than those using a conventional, unstructured, consensus meeting approach. They also express less decision satisfaction than those relying on the Delphi technique.

THE DELPHI TECHNIQUE

The Delphi technique is a method for collecting, organizing, reviewing, and revising the opinions of a group of individuals who never actually meet. This procedure, which is directed by a nonparticipating coordinator, generates a group decision without physically assembling members. Ideas are solicited and provided via questionnaires. The Delphi technique typically involves the following steps:

- **Solicit input:** The coordinator sends initial questions to members via a mail, fax, or e-mail survey.
- **Independently generate ideas:** Members brainstorm and then include their opinions and ideas on the survey, which is returned to the coordinator on completion.
- **Summarize input:** The coordinator summarizes the input received from members in a way that maintains member anonymity.
- **Distribute summary:** The coordinator sends the summary of everyone's opinions to all group members.
- **Revise, refine, and prioritize earlier input:** After reading the summary of opinions, members are given the opportunity to revise their earlier input, refine

ideas, comment on idea strengths and weaknesses, prioritize the opinions being considered, and identify new ideas. When finished, they send their input to the coordinator.

- **Repeat as necessary:** The third through the fifth steps described earlier are repeated until members have no further input to add.
- **Form final decision:** If a clear consensus emerges after the final round of surveys, the exercise is finished. Alternatively, the members may be asked to rank or rate the final decision options. In this case, the group decision is the alternative with the most favorable rating or ranking.

By requiring members to work independently, the Delphi technique can promote accountability, decrease social loafing, equalize participation, eliminate the biasing effect of domineering members, prevent impaired communications stemming from unproductive disagreements and conflict, avoid the logistical problems (e.g., scheduling) that occur when trying to assemble a dispersed group, eliminate production blocking, and ensure that a premature decision is not made before all ideas are expressed. In addition, the anonymity of group members' input can decrease evaluation apprehension and minimize pressure to conform.

Research has shown that groups structured according to the Delphi technique are more satisfied than both nominal and conventional consensus groups. However, the Delphi process can take a long time. Some estimates indicate that this process, when conducted by postal mail, takes about 44 days on average. Another limitation of this technique is that it completely eliminates direct interaction among group members, which can lead to fruitful synergies under the right conditions.

THE STEPLADDER TECHNIQUE

The stepladder technique is a group decision-making strategy that staggers the entry of members into a group. Like the nominal group and Delphi approaches, the stepladder technique facilitates both the generation and evaluation of ideas. Unlike its predecessors, the stepladder approach allows groups to form a final decision collaboratively and collectively rather than having an outside party derive the group decision by combining independent inputs.

The stepladder technique commences by forming a two-person core group. These two members begin discussion of the problem at hand by presenting their

individual ideas to each other. When they feel they understand each other's ideas, a third member is brought into the core group. This member presents ideas and a preliminary discussion ensues. Next, a fourth member is brought into the core group to present ideas and then participate in the preliminary discussion. This process continues until each member of the team has joined. Once all members are present, the group works together to form a final decision.

The stepladder technique has four ground rules:

1. **Allot sufficient individual problem-solving time:** Each member must have adequate time to think about the problem at hand before joining the core group.
2. **Require entering members to speak first:** On entry, a group member must present all ideas before hearing the core group's preliminary solutions.
3. **Allot sufficient group discussion time:** An adequate amount of discussion time must be allotted to discuss the issues immediately after an entering member presents ideas.
4. **Delay final decisions until all are present:** The group must be fully formed with all members present before a final solution is determined.

By requiring each member to present ideas independently and without knowledge of others' ideas, the stepladder technique may promote accountability, decrease social loafing, decrease conformity, and equalize participation. Moreover, the stepladder technique can minimize the biasing effect of domineering teammates by giving each member an uninterrupted presentation opportunity on entering the group. Finally, by instructing groups to wait until all are present before forming a final decision, the stepladder approach can prevent groups from arriving at solutions prematurely, before all members have exhausted their supply of ideas.

Compared with members of groups using a conventional, unstructured, consensus meeting approach, members of stepladder groups have reported feeling less pressure to conform. Following their group decisions, stepladder members are also more inclined to consider their group friendly and believe that they collectively agreed on a final product, worked unusually well together, worked hard on the task, proceeded in an organized manner, and devised a better-than-average solution. Tests of the technique have shown that stepladder groups do tend to produce higher-quality decisions than conventional groups. This is true for

time-restricted, face-to-face stepladder groups where each step is monitored by an outside coordinator who enforces time limits at each phase. It is also true for self-paced, face-to-face stepladder groups that self-regulate and determine how much time is needed at each step. Research has cast doubts on whether the time-restricted stepladder technique improves the decisions of dispersed, computer-mediated teams using text-based software to collaborate online. However, the self-paced stepladder technique has been shown to improve the quality of dispersed audioconferencing groups collaborating by telephone.

GROUP DEVELOPMENT

Group or team development refers to the process by which members of newly formed work teams learn about their teammates, establish their roles and responsibilities, and acquire the *task work* and *team-work* capabilities required to coordinate their effort to perform effectively as a team. Work group development pertains to the team as a whole (i.e., all members are new to the team), distinguishing this process from group socialization, which refers to the assimilation of new members into an existing team with an ongoing history. The amount of time it takes for a team to develop is variable and, although precise time frames are not established, the process is presumed to take longer when the team task entails greater complexity, interdependence, and coordination and less time when there is less demand for the integration of team members' knowledge, skill, and effort. The process is important because team development is assumed to be a necessary, but insufficient, precondition for team effectiveness. That is, work groups and teams cannot achieve goals and meet performance expectations until essential task work and teamwork skills have developed. However, other contingencies that influence team performance have to be resolved before teams can perform effectively; such factors are the focus of team effectiveness models and research. Finally, although team training and leadership interventions have the potential to enhance team development, it is a process that generally unfolds naturally without intentional intervention. Thus the potential for improving team development (and team effectiveness) in many organizations is high.

THEORIES, MODELS, AND APPROACHES

Time is central in all models of group development. How this temporal process has been treated, however, distinguishes different conceptual approaches: stage, punctuated equilibrium, and integrated models, and more recent systems-oriented approaches.

Stage Models

Until relatively recently, most theories of group development were based on descriptions of the *stages* groups passed through as the developmental process unfolded. Although there are many such stage models,

their basic characteristics are captured very well by B. W. Tuckman's (1965) widely cited model of group development. He reviewed the group literature—defined by therapy, T-group, natural, and laboratory group studies—and proposed that groups go through the developmental stages of *forming*, *storming*, *norming*, and *performing*.

As team members are first brought together during the formation stage, they cautiously begin to explore the group and attempt to establish some social structure. This stage is characterized by feelings of excitement, anticipation, and optimism; pride in being chosen for the project; initial, tentative attachment to the group; and some fear and anxiety about what lies ahead. Members attempt to define the nature of the group task and to establish how they will accomplish it. They try to determine acceptable group behavior and deal with group problems. Discussions are often characterized by abstract, lofty concepts and issues, but members may also express impatience with the failure of the group to be more task focused.

As team members begin to realize that defining the task is more difficult than expected, they move to the difficult storming stage. They focus inward and become testy, impatient, and blameful over the lack of progress. Members argue about what actions the group should take. There is defensiveness, competition, disunity, and jealousy. Different factions may form as conflict within the group progresses. Members may experience mood swings as they wonder about the project's potential for success.

As the group is finally able to reconcile competing loyalties and responsibilities, it begins to firmly establish ground rules, roles, and status. During this norming stage, members reduce emotional conflict and become more cooperative. There is more friendliness, personal confiding, and harmony. Members express criticism constructively and attempt to avoid conflict. They develop a sense of group cohesion and common goals.

As these normative expectations take hold, the group moves to the performing stage. Members have more insight into personal and group processes and a better understanding of each other's strengths and weaknesses. They are able to prevent group problems or work through them when they arise. Members become closely attached to the team and satisfied with its progress as they move toward their common goal.

This stage model of group development is a classic and representative of many other similar such models.

It provides a rich description of the social interaction process group members experience as they struggle to resolve task uncertainty, interpersonal ambiguity, and conflict as they create a social structure to guide their interactions. However, this and similar stage models are not specific to work group development, where the organizational setting and task requirements are more salient and important. Thus most stage models tend to heavily emphasize group development centered on social interaction, with far less attention to development around task-driven interactions that are important to coordination in work teams.

Punctuated Equilibrium Model

Other descriptive research on team development has produced a notable variation to the stages and underlying process of group development addressed by stage models. In two studies, C. J. Gersick (1988, 1989) examined eight student groups and eight organizational project teams as they worked to accomplish a group objective. The project teams possessed a single project objective and a finite life span (i.e., project deadline), but the length of the deadline varied across groups. Findings from her qualitative analysis indicated that the project groups established an immediate pattern of activity toward their objective, with little apparent progress, that persisted until a transition point about halfway to the project deadline. At that point, the groups dropped old agendas, adopted new perspectives, and made major progress toward the completion of their project. This transition was characterized as a *punctuated equilibrium*, a discontinuous shift and realignment, that significantly altered the pattern of group activity. This finding points to the importance of external factors (i.e., temporal entrainment to the project deadline) as well as internal factors to group development and activity.

Integrated Models

Although some scholars view stage models and the punctuated equilibrium model as contradictory, others view them as distinctive yet complementary. For example, one study examined 25 student project groups and concluded that the models are largely complementary. Key factors distinguishing the approaches were the content that was used for coding group activities and the unit of time for observations.

Content that addressed group processes and structure and more microtiming tended to support the linear developmental process inherent in the stage approach, whereas content that addressed the group's approach to their task and more macrotiming supported the punctuated equilibrium approach. These findings suggest that both perspectives have value for describing the process of group development.

Other researchers have also taken an integrative perspective, asserting that work teams need to develop and combine task work and teamwork skills across nine stages of development that combine both stages and a punctuated transition. In phase one, teams proceeded through four stages of forming, storming, norming, and performing and then made a transition to phase two that yielded improved task work and teamwork. Although data evaluating this model were based on a small number of teams, the researchers found that better performing teams exhibited more effective teamwork behaviors including team spirit, cooperation, coordination, and adaptability; developed better role clarity; and evidenced more consensuses about teamwork over time. Thus the research provided support for a developmental process that increasingly integrated both task work and teamwork skills over time, with that integration important to team effectiveness.

System-Oriented Approaches

More recent theory on team development and performance has adopted an organizational systems perspective. Teams are embedded in an open, yet bounded, organizational system composed of multiple levels: individual team members, the team, and an embedding organizational context. This broader system sets *top-down* contextual constraints on team functioning. Simultaneously, team development, performance, and effectiveness are complex *bottom-up* phenomena that emerge over time from what individual team members think, feel, and do, and how they interact with other team members. Theories of team development that are emerging from this more recent perspective are sensitive to critical conceptual issues of task interdependence (i.e., task-driven demands for interaction and coordination), temporal dynamics (i.e., different temporal processes—linear and cyclical or episodic—exert different influences on team development and performance), and multilevel influences (i.e., team development and performance are influenced

by what individuals think, feel, and do; the social structure that members enact to guide the group, and higher-level organizational factors).

One example of representative work within this perspective is a model of *team compilation* that integrates team development and performance; team performance at any given point in time is viewed as a consequence of a continuous developmental process. Temporal dynamics are both linear and cyclical, representing developmental processes and task episodes, respectively. Team capabilities improve with linear time prompting transition to more advanced skill acquisition. Within a phase, task episodes provide opportunities for learning. Team compilation is viewed as an emergent multilevel phenomenon such that knowledge, skills, and performance outcomes compile successively upward across levels from an individual self-focus to dyadic exchanges to a dynamic and adaptive team network. Relative to the other approaches to group development, this emerging theory is more process oriented and sensitive to temporal characteristics and the interconnectedness of teams in the organizational system. Because this perspective is relatively recent, research is sparse; but preliminary findings are encouraging.

SUMMARY

Perspectives on work group and team development have progressed from descriptive stages and punctuated transitions; to integrated approaches that combine these complementary processes; to more recent system-oriented approaches that view team development (and performance) as complex phenomena that are embedded in the organizational system with influences from multiple levels, strongly influenced by the workflow interdependence of team tasks, and emerge dynamically and adaptively over time as teams continuously acquire expertise. As teams increasingly become the basic organizing structure of work, understanding and improving the processes will assume greater importance. Given that developing integrated task work and teamwork skills is a precondition for team effectiveness, it is remarkable that many organizations do relatively little in the way of intervening to improve team development; for the most part, teams are assembled and left on their own. However, team training and team leadership are key leverage points for enhancing the developmental process by intervening before or as teams are formed (team training) and

as they proceed through the developmental process in the work setting (team leadership and coaching).

GROUP DYNAMICS AND PROCESSES

For most people in work organizations, the organization as a whole is a relatively abstract entity. Their day-to-day work experience is shaped far more by the work group, team, department, or work unit than by the organization as a whole. The work group is their direct social environment at work and the most important social influence on how they experience their work. Moreover, organizations are increasingly

structuring work to be group or team based, where groups and teams rather than individuals are responsible for production and performance. This requires people to work in close cooperation with their fellow group members; and it makes coordination, cooperation, and communication between group members critical elements of task performance. Obviously, then, understanding how work groups function, what causes specific group processes, and what the consequences of specific group processes are is of critical importance to theory and practice in industrial/organizational (I/O) psychology. Understanding these processes is the domain of group dynamics, or group processes.

The causes and consequences of group processes are typically understood within an input–process–outcome (IPO) framework, in which group processes (what happens in the group during task performance) are seen as the mechanism through which group inputs (resources internal and external to the group, and the organizational context) are translated into group outcomes (productivity, performance, or some other indicator of group effectiveness). In recent years research has highlighted group processes as critical in this respect, including group information processing; group conflict; group members' shared understanding of, and shared feelings about, the task situation; and group efficacy.

INPUT–PROCESS–OUTCOME MODELS OF GROUP EFFECTIVENESS

Most attempts to understand group dynamics implicitly or explicitly take an IPO perspective. Inputs refer to what is *given* at the outset of task performance. Inputs include factors that flow from team composition—such as group member personality, knowledge, skills, and abilities—but also factors that are more external to the team—such as the organizational context in which the group performs its tasks. Processes refer to what actually takes place in the group during task performance, highlight what happens in the interaction between group members, and underscore group members' thoughts and feelings about the group and group task performance. Obviously, the focus in trying to understand group processes is on factors that may be assumed to affect desirable and undesirable outcomes of group interaction. Outcomes in principle are all variables that might be influenced by group inputs and group processes. Not surprisingly, however, in I/O

psychology the emphasis typically is on group outcomes that can be seen as indicators of group effectiveness, such as group productivity and performance, or on variables that may be seen as more distal indicators of effective group functioning such as group member turnover and satisfaction.

Originally, group processes were understood within this IPO perspective as being caused by group inputs. Group process was primarily seen as the mechanism explaining the relationship between group inputs and group outcomes. An alternative perspective in which group processes are seen as mechanisms that may be influenced to affect the relationship between group inputs and group outcomes is equally viable, however. In the latter perspective, specific group processes are not seen as the more or less inevitable consequence of particular input factors but rather as mechanisms that may be influenced, for example, by team leadership or management practices, in attempts to achieve positive group outcomes and prevent negative group outcomes. Importantly, the perspectives do not contradict each other. Particular group inputs may be likely to engender specific group processes, whereas at the same time group interventions may render these associations between inputs and outcomes more or less likely. For research and practice in group dynamics, it is therefore important to understand both how group input may affect group processes, and group outcomes through group process, and how group processes may be used to translate group inputs into desirable outcomes.

KEY ISSUES IN GROUP DYNAMICS AND PROCESSES

As more and more organizations use groups and teams for knowledge-intensive work, an issue that seems to increasingly assume center stage is a group's ability to process and integrate large amounts of task-relevant information, as well as use this information in creative and innovative ways. Research and development teams are prime examples of teams faced with such tasks; but the same holds, for example, for the top management teams found in many of today's organizations. The challenge to such groups and teams is all the bigger, because such groups are often quite diverse in their composition, including members with different demographic, educational, and functional backgrounds, and this diversity may introduce a wide range of task-relevant information, knowledge, and

expertise that groups ideally would use in their task performance. Thus group information processing and decision making is one of the key issues in understanding and managing group dynamics.

A related but distinct issue is group conflict. Whenever people work together, conflicts may arise. These conflicts may concern the task itself as well as the relationship between group members. Especially diverse groups that have to deal with complex issues may be prone to such conflicts. Conflicts can be problematic, because they may disrupt group functioning and decrease satisfaction among group members. However, not all conflicts appear to be equally disruptive—task-related conflicts tend to be less problematic than relationship-oriented conflicts. Moreover, there is also evidence that at least under certain circumstances task conflict may actually be productive, because it may stimulate more thorough and creative thinking among group members. Group conflict in particular thus seems a group process that requires careful management; although it may often be disruptive, it may also lead to positive outcomes.

More and more evidence points to another aspect of group processes that may have an important impact on group outcomes: the extent to which thoughts and feelings about the group and the group's task are socially shared among group members, that is, the extent to which group members have similar thoughts and feelings about the group and the task. This is the area of research in what are called team mental models and task mental models—group members' understanding of their team and the way it functions and of the team task and the way it should be performed. This research suggests that as mental models of the team and the task become more socially shared (i.e., as group members hold more similar mental models), the influence of these mental models on group task performance grows; and groups may function more effectively and efficiently because these shared mental models provide guidance that not only contributes to individual performance but may also help coordinate group member efforts. Research has similarly suggested that groups may share feelings; and as feelings become more socially shared, they exert a stronger influence on group interaction. More generally, research suggests that group members' thoughts and feelings exert a greater influence on group processes and performance the more they are socially shared.

Another factor that is important to group performance is perceptions of group efficacy: the belief that

the group is capable of achieving its goals. The perception that an individual is able to achieve a goal is an important factor in translating motivation into action, and essentially the same holds for groups. Higher group efficacy (or group potency) tends to be associated with more effort and persistence in task performance and ultimately with better performance. Somewhat related to this is the notion of group cohesiveness—group members' attraction to the group. At least under certain conditions, high cohesiveness may engender group member efforts that result in better performance.

From an applied perspective, this suggests that the effective management of work groups and teams includes the management of group processes, such that the potential in group inputs is realized; and potentially negative effects of group inputs, such as (relational) conflicts, are prevented. Among other things, this requires fostering group motivation and ability to thoroughly exchange, process, and integrate task-relevant information and perspectives; the careful management of group conflict to reap its potential benefits without suffering its potentially disruptive consequences; and facilitating the development of an (appropriate) shared understanding of the team and the task. This may involve member selection (e.g., selecting members with appropriate knowledge, skills, and ability), leadership to motivate high task performance and to build the trust between group members that is necessary to effectively deal with conflicts, and collective rather than individual training to develop a shared understanding of the team and the task. It also helps to keep the work group or team together for a more extended period of time so the team can benefit from the initial time investment required to achieve these positive influences on group processes.

GROUP MENTAL MODEL

See TEAM MENTAL MODEL

GROUPS

Organizations seeking to promote productivity, better service, fewer errors, and improved safety as well as remain competitive in changing environments are turning to work teams and groups. Work teams have become a preferred performance improvement intervention in the last decade. So now we have a plethora of theories, methodologies, tools, and strategies to understand and facilitate teamwork in organizations. Both the science and practice of team performance has evolved and matured, making significant progress. But why and when do organizations deploy teams? Are all work teams created equal? Are all groups in organizations the same? This brief section addresses these questions. What follows is an attempt to clarify and elaborate some of the key features that characterize work teams and groups in organizations.

First, why do organizations use, dispatch, and compose work teams and groups today?

WHY ARE GROUPS USED IN ORGANIZATIONS?

Teams and groups are used for a variety of reasons, from brainstorming activities to problem solving issues to manufacturing products. Teams and groups are present in the floor shop as well as in the boardroom. They are used to perform surgery, fly planes, operate power plants, launch the space shuttle, drill for oil, and secure the peace of nations. But work

teams and groups are mainly (not always) used when tasks are complex, difficult, and dynamic and where the consequences for errors are high. Also, work teams are best when redundancy is needed and the context in which they will perform is ill-defined as well as where team members have to process lots of information from different modalities. So the kinds of tasks teams or groups need to execute matter. The environment and the demands on team members matter.

And if errors are costly, they matter even more. In sum, work teams (and some groups) perform best and are needed when organizations have fluid environments typified by rapidly evolving and ambiguous situations, no right answers, information overload, intense time pressure, and severe consequences for error.

TEAMS

Many definitions of work teams have been advanced over the last two decades. Taken together, work teams are complex social and dynamic entities characterized by the following:

- there are two or more members;
- they hold meaningful task, goal, and feedback interdependencies;
- they interact routinely;
- they interact adaptively;
- they have a shared common and valued vision;
- they are hierarchically organized;
- they have a limited life span;
- they have expertise, roles, and functions that are distributed;
- they engage in cycles of performance; and
- they are embedded in an organizational environment that influences its processes and performance outcomes.

This definition is an umbrella for typifying the kind of teams found in industry, business, agencies, and the military.

GROUPS

Groups are in the same continua as teams, but usually work groups have no task interdependency and the expertise is not distributed. Work groups are loosely coupled social entities that are brought in to solve a specific problem or generate ideas about how to improve a situation, such as a task force or brainstorming group. Their life

cycle is short and group members have no shared history or future. Of course, there are exceptions.

Is the distinction between these two entities important? Well, in practice it might not be. But in research, it is. To build the science of team performance, we must be clear on how research findings generalize, to what kind of team or group the results matter. Again, all work teams are not created equal and neither are groups.

GROUPTHINK

Groupthink is a term coined by Irving Janis in 1971 to describe a premature concurrence-seeking tendency that interferes with collective decision-making

processes and leads to poor decisions. It is characterized by deterioration in group member mental efficiency, reality testing, and moral judgments that result from in-group pressures to seek consensus. It is what happens when the task demands on a decision-making group are overwhelmed by the social demands to reach consensus. When experiencing groupthink, members tend to make simplistic statements about the issues and more positive in-group references than those in nongroupthink cases.

Groupthink theory has become an influential framework for understanding the origins of group decision-making fiascos and has been widely cited in a variety of disciplines including psychology, business, political science, and communication. The appeal of the concept is evidenced by the ease with which it can be applied to numerous group decisions and the potential for groupthink to occur in various work situations.

Groupthink is likely when members

- are in a highly cohesive group;
- perceive a stressful situational context such as time pressure;
- perceive the task to be important, difficult, and involving; and
- are striving for unanimity rather than evaluating alternative courses of action (i.e., concurrence seeking tendency).

Group cohesion may be a function of mutual attraction, comradeship, enthusiasm, and devotion to a common course; desire to belong to the group; or loyalty to a leader. Other antecedents of groupthink may be structural and procedural faults of the group, including insulation, promotional (or directive) leadership, lack of norms requiring methodological procedures, and homogeneity of members’ social backgrounds and ideology.

Groupthink theory identifies specific symptoms of defective decision making and prescribes a number of concrete and useful remedies for avoiding them. The original symptoms of groupthink identified by Janis (1972) are as follows:

- **An illusion of invulnerability:** Members ignore obvious danger, take extreme risk, and are overly optimistic.
- **Collective rationalization:** Members discredit and explain away warnings contrary to group thinking.
- **An illusion of morality:** Members believe their decisions are morally correct, ignoring the ethical consequences of their decisions.

- **Excessive stereotyping:** The group constructs negative stereotypes of rivals outside the group.
- **Direct pressure for conformity on dissidents:** Peers pressure members of the group who express arguments against the prevailing group's stereotypes, illusions, or commitments, viewing such opposition as disloyalty.
- **Self-censorship:** Members withhold their dissenting views and counterarguments.
- **Illusion of unanimity:** Members perceive falsely that everyone agrees with the group's decision—silence is considered consent.
- **Reliance on self-appointed mind guards:** Some members appoint themselves to the role of protecting the group from adverse information that might threaten group complacency.

Research suggests that additional symptoms may include the following:

- **Group insulation:** Failure to initiate or maintain contact with an opposition group and lack of coordination with third-party mediators.
- **Creation of time pressure:** Failure to extend the time period for reaching a decision.
- **Lack of impartial leadership:** Less available information is used and few solutions are suggested when leaders are directive.
- **Decision making:** Lack of methodical decision-making procedures.

By facilitating the development of shared illusions and related norms, these symptoms are used by groups to maintain *esprit de corps* during difficult times. The major thrust of groupthink theory is that the presence of a number of the previous symptoms increases the probability that a group will elicit groupthink. That is, the more symptoms of groupthink, the more unfavorable the outcomes.

Groupthink may be avoided if the group does the following:

- **Understands groupthink:** The group is made aware of the causes and consequences of groupthink.
- **Has an open climate:** The leader is neutral when assigning a decision-making task to a group, initially withholding all preferences and expectations. This practice can be especially effective if the leaders consistently encourage an atmosphere of open inquiry with free discussion, nonjudgmental attitudes, and acceptance of divergent thinking. The leader gives high priority to airing objections and doubts, and

is accepting of criticism. Groups are divided into two separate deliberative bodies as feasibility is evaluated.

- **Avoids being too directive:** The leader exercises the leadership role by avoiding being too directive. It is important that the leader avoid exerting undue influence on other group members.
- **Has coping mechanisms:** Groups should be provided with some means of coping with decision-making stress.
- **Avoids isolation:** Outside experts should be included in vital decision making to provide critical reaction to the group's assumptions. Tentative decisions should be discussed with trusted colleagues from outside the decision-making group. In this way the group avoids isolation with limited data and few perceived choices. The organization should routinely follow the administrative practice of establishing several independent decision-making groups to work on the same critical issue or policy.
- **Assigns members the role of critical evaluator:** Each group member should be a critical evaluator with the role of devil's advocate assigned to several strong members of the group. After reaching a preliminary consensus on a decision, all residual doubts should be expressed and the matter reconsidered. The group should be forced to reexamine its assumptions and rationalizations and consider unpopular alternatives. A sizable amount of time should be allocated specifically to surveying all warning signals from rival groups and organizations.

RESEARCH SUPPORT

Janis (1972) first developed the concept of groupthink through qualitative analyses of defective decision-making cases such as the appeasement of Nazi Germany, the Bay of Pigs, Pearl Harbor, the North Korean invasion, the escalation of the Vietnam War, and the Watergate cover-up. He compared the decision-making processes involved in these fiascoes with those cases in which there was more effective decision making, such as the Cuban Missile Crisis and the Marshall Plan. In developing groupthink theory, Janis highlighted the defective search and appraisal process that could be attributed directly to group pressures acting on members and stemming directly from their desire to protect and maintain group cohesion.

Philip Tetlock (1979) conducted a more quantitative test of Janis's theory by conducting a content analysis of public statements made by key decision makers involved in groupthink and nongroupthink

decisions. Results of this analysis indicate that decision makers in groupthink situations had more simplistic perceptions of policy issues and more positive references to the United States and its allies. However, these decision makers did not engage in more out-group stereotyping.

Since its original conception, the groupthink model has been widely investigated in experimental settings, and there are about two dozen empirical studies of groupthink. The studies directly testing the model use one or a combination of three methods: case study, laboratory experiment, and content analysis. Although most studies have examined the antecedents of groupthink and defective decision making, researchers have attempted to expand on the model and provide the underlying psychological mechanisms producing groupthink, such as social categorization, compliance and internalization, and group polarizations.

Laboratory studies have mainly focused on the antecedent conditions of groupthink including leadership, group cohesiveness, external threat, and so on. These studies have demonstrated that directive leadership style with more mind guarding and more self-censorship is predictive of groupthink. In addition, there is generally support that lack of decision-making procedures increases groupthink; and external threat, particularly time pressure, appears to promote symptoms of groupthink and defective decision making.

However, contrary to Janis's predictions, laboratory studies have found little or no support for group cohesion as a predictor of groupthink. However, these studies have been criticized for operationalizing groupthink poorly or inappropriately because members may not have perceived themselves as group members. Moreover, although insulated groups do seem to consider fewer alternatives and make poorer decisions, they do not have an illusion of invulnerability and do not consult with experts less often than do less insulated groups.

Overall, results of experimental studies provide only partial support for the groupthink model, and there are no firm conclusions regarding its antecedents. Researchers have attributed null or contradictory results of the experimental studies of groupthink to

- testing the model partially by including only a subset of antecedent conditions,
- failure to fully capture the original meanings of the antecedent conditions,

- failure to include all symptoms of groupthink and defective decision making, and
- failure to use a decision-making task on which solution quality ranges from very poor to very good.

In practical terms, research has applied the groupthink model to various managerial domains, such as decision making, leadership, and the management of organizational teams. In these domains groupthink has been regarded as a detrimental group process and, as a result, many training programs addressing leadership and team performance have incorporated various strategies to avoid groupthink in the workplace. There has been little empirical work done to demonstrate groupthink's negative implications in organizations. However, the few studies that have been conducted provide evidence that groupthink hinders the effectiveness of work teams.

H

HARDINESS

Hardiness consists of three interrelated belief systems people have about their relationship to their world. *Commitment* refers to people's ability to find meaning in events that happen to them. People who are high in commitment feel involved in and engaged by events in their lives rather than feeling alienated, disengaged, or disconnected. *Control* refers to the sense that, through effort, people can influence the world. People who are high in control feel capable of responding to events in their lives rather than helpless. *Challenge* refers to the belief that to be fulfilled, people must gain wisdom from experience, rather than living a life that is completely safe, secure, and routine. People who are high in challenge tend to view potentially stressful events as opportunities for personal growth, rather than feeling threatened by the world. Hardiness researchers regard these three belief systems as reflecting people's dispositional resilience to the detrimental effects of stressful events as well as their ability to summon courage in the face of adversity.

In the late 1970s, a research team led by Salvatore Maddi and Suzanne Kobasa conducted a longitudinal study of business executives. They were particularly interested in differentiating between executives who thrived under intense stress and those who experienced great personal and performance difficulties. They identified the hardiness belief systems as crucial to maintaining health and performance under stress. For industrial/organizational (I/O) psychologists, perhaps the most compelling aspect of their theoretical model was their research-supported contention that

hardiness could be taught, which has important practical implications for stress management programs. Maddi and Kobasa's (1984) research stimulated hundreds of studies on hardiness as well as numerous doctoral dissertations. Thus there is a substantial empirical literature from which to draw conclusions about the effects of hardiness on work-related outcomes.

FINDINGS FROM HARDINESS LITERATURE

Much research has studied the effects of hardiness on health-related outcomes. One of the most common outcomes examined in this literature is burnout, defined as a syndrome of emotional exhaustion, disengagement, and a loss of feelings of accomplishment that is common in occupations requiring intense interpersonal interactions with clients or customers. Several studies have established a negative relationship between hardiness and burnout, particularly for service professions such as nursing and teaching. Hardiness also is associated with desirable outcomes such as job and life satisfaction, optimism, positive affect, perceptions of support, and general well-being; and it is negatively related to outcomes such as anxiety and depression. Finally, several studies report modest positive relationships between hardiness and physical health, but the connections between hardiness and physiological reactions to stress are not well understood.

Less research has examined work outcomes such as job attitudes and behavior. Although there are some exceptions, hardy employees appear to hold more favorable views of their jobs and are more committed

to their employing organization. Other studies suggest that hardy individuals may be better organizational citizens and better able to maintain effective performance under stress. The relationship of hardiness to other occupational outcomes, such as absenteeism and injuries, lacks definitive conclusions. Conclusions vary greatly across studies of absenteeism; the limited research on injuries suggests that hardy workers may be less likely to suffer illnesses or injuries requiring hospitalization.

Ample research has examined indirect effects of hardiness on work and health outcomes, including hardiness-related individual differences in how people appraise potentially stressful events, choose coping strategies, and access social support. Hardy people tend to appraise stressful events as less threatening and more controllable. They feel more confident about their ability to cope with stressful events and classify fewer experiences as undesirable. Hardy people also are more apt to use adaptive coping strategies such as active or problem-focused coping and avoid maladaptive strategies such as denial and disengagement. Finally, hardy people generally tend to build larger, more effective social networks, suggesting that they have more potential support when coping with workplace stressors. They also report higher levels of social support from both coworkers and supervisors. It is unclear whether these perceptions reflect higher levels of received support or a lower need for social support. However, in either case, hardy people seem better equipped to cope with stressors at work. Taken together, these findings show that hardiness influences many of the causal pathways through which stressful events influence health.

One of the most frequently examined issues in the hardiness literature concerns whether hardiness moderates the relationship between experiencing potentially stressful events and suffering adverse consequences of those stressors. This literature is replete with inconsistent findings. Some of the inconsistencies observed may be caused by differing definitions of stress. For example, hardiness researchers have defined stress in terms of exposure to events most people consider stressful, the perceived intensity of a stressor, frequency of exposure to a stressor, the number of major life events experienced, and the levels of perceived role demands they face. These differing definitions of stress probably account for some of the conflicting findings

in this literature. Thus although there is ample evidence to suggest the beneficial effects of hardiness on health and work outcomes, the exact mechanisms through which these effects occur are unclear.

UNRESOLVED ISSUES

A few unresolved issues present challenges for hardiness research. First, the central propositions of hardiness theory are somewhat more complicated than those tested in most empirical research. For example, hardiness theory suggests that hardy employees should experience less stress and be more resistant to the effects of stress. This implies that the effects of hardiness on outcomes should be expressed through stress response processes rather than directly on outcomes of interest. Second, some theoretical depictions of hardiness suggests that high levels of all three parts are required, whereas researchers typically examine each part separately or average across the three components to form a total score. Finally, some research has begun to separate the positive and negative components of each belief system. For example, people may differ in their tendencies to adopt entirely positive, largely negative, or somewhat more conflicted belief systems. The positive and negative elements of these belief systems may exert distinct effects on health and performance processes. Thus much literature has demonstrated the importance of hardiness for I/O psychology but has also identified some exciting challenges for future research.

HAWTHORNE STUDIES/ HAWTHORNE EFFECT

The Hawthorne Studies and the Hawthorne Effect are threads through management schools and associated research from before the Great Depression to the present. They can be viewed from at least four vantage points. The Hawthorne Studies themselves were a series of collaborative investigations at the Hawthorne Works of Western Electric. The researchers began with a criterion of productivity and first studied environmental changes in illumination, encountered anomalies because production increased when illumination decreased to very low levels, and finally shifted toward recognition of social influences and personnel counseling. From one perspective, they linked the scientific management and the human relations movement schools. From a second standpoint, the studies attracted multiple disciplines interested in organizations (sociology, industrial, social, and then organizational psychology, organizational behavior, and human resource management). From a third outlook, they provide numerous lessons concerning the history of these fields in the unquestioning acceptance of secondary sources and in methods for studying history. From a fourth, methodological perspective, the Hawthorne Effect was defined as a confounding and biasing factor in intervention research that resulted from research participation (status or difference perception of participants). An example of how the effect has penetrated current methodological thinking is the widespread citation of the term in method and conclusion sections of contemporary research articles. This entry approaches the Hawthorne Studies from three vantage points:

1. Genesis and growth of the studies
2. Key findings of the Hawthorne Studies
3. Role of the Hawthorne Studies and Hawthorne Effect in shaping the history and trajectory of industrial/organizational (I/O) psychology and related disciplines

GENESIS AND GROWTH

Ostensibly, the Hawthorne Studies began as attempts to study such factors as illumination and work breaks. In that sense they derived from a school of thought that was dominant in management thinking. The scientific management school, although sensitive to worker concerns, believed that extrinsic environmental factors accounted for most of the variance in performance and productivity; worker attitudes were not viewed as important at this time, but the seeds were sown with the development of the concept of attitude. Fritz Roethlisberger and William Dickson described multiple studies conducted at the Hawthorne Works of the Western Electric Company in Cicero, Illinois, between 1924 and 1932. They published *Management and the Worker* in 1939, but this book was preceded by publications by Thomas Whitehead and Elton Mayo. Mayo, for example, worked in several ways to guide, motivate, and popularize the Hawthorne Studies, publishing a well-known book in 1933 titled *The Human Problems of an Industrial Civilization*. The personnel interviewing and subsequent counseling programs were unique contributions of the research program, larger in scope than the other studies (encompassing more than 25,000 workers at one point) and much less well remembered; and yet they continued long after the other experiments ended (Katzell & Austin, 1992).

KEY FINDINGS

The Hawthorne studies represent an early instance in which a firm, in this case the Western Electric Company, collaborated with a group of academicians in an effort to improve individual productivity and thus presumably organizational efficiency. The academics, including Elton Mayo and T. N. Whitehead, were faculty of the Harvard Business School. The original experiments dealt with modifications of illumination, wage incentives, and rest pauses—topics that would have gladdened the heart of F. W. Taylor and the scientific management school. What captivated psychologists and others were not those substantive results but the serendipitous findings highlighting the importance of social relationships: team development, informal supervision, and group norms. Specifically, the researchers found it necessary to shift (and then explain their shift) from a scientific

management focus toward one that emphasized development of group norms and their enforcement through informal leadership.

Another prominent aspect of the work at Hawthorne was that it involved systematic field research—including time-series, experimental, and observational techniques. The researchers set up specific conditions that varied within and across groups. They tracked these conditions over many weeks and tallied production counts for the groups in the Relay Assembly Test Room and the Mica Splitting Room. The field experiments of Frederick Taylor and Frank Gilbreth had been less sophisticated in terms of research design and data analysis and carried out in the tradition of management rather than behavioral science. In the Hawthorne Studies, however, the interventions were supervised by teams of managers and behavioral scientists, and there were systematic, even if imperfect, efforts at experimental and statistical controls. An entire domain of *Hawthorne bashing* became quite popular after the reports of the research were promulgated, extending as far as a Marxist critique based on the concept of class struggle. It is possible to divide such critiques into methodological and learning hypotheses and attempt to refute the learning hypothesis adherents. One interesting research tactic employed by several individuals was to locate and interview individuals who had participated. Such combinations of qualitative and quantitative approaches to the study of history ought to become more influential.

As with many historical *facts* in I/O psychology, however, myth mixes with the mundane. Charles Wrege exposed many misconceptions in his dissertation, but this did not stop textbook authors from perpetuating the myths. Olson, Verley, Santos, and Salas (2004), in a recent analysis of textbook coverage of the Hawthorne studies, document the misconceptions in several ways. They reviewed the frequency of mention of various parts of the studies in 21 books and presented a table containing definitions of the effect provided by 13 authors. One way that confusion is sown is in descriptions of the layout and sequence of the studies, another in the ascription of greater importance than warranted to Elton Mayo, and a third in a failure to consult primary sources.

ROLE AND EFFECTS ON INDUSTRIAL/ ORGANIZATIONAL PSYCHOLOGY

One of the key effects of the Hawthorne Studies was as a general warning about alternative interpretations for

research findings. This warning was especially true for large-scale field research. As a blanket tocsin the general Hawthorne effect was perhaps overused. Links to experimenter and expectancy effects might provide a more circumscribed and useful rationale. Undoubtedly, more specific interpretations of bias in research outcomes are preferred in contemporary circles.

Although the critics make valid points, they also miss important points. Despite demonstrable flaws of design and analysis, it was those studies and their philosophy that helped launch the human relations movement and the organizational branch of the I/O discipline. Study of the history of the field, in addition, can be enhanced through consideration of how the myths were established and perpetuated, including some of the techniques used by historians.

HIGH-PERFORMANCE ORGANIZATION MODEL

The contemporary flexible, high-performance organization model is a primary alternative to the classical bureaucratic model, popularly known as *Taylorism*. Several historical trends have contributed to the development of the high-performance model.

Beginning in the 1930s, increased attention was focused on the human impact of work, especially in assembly-line type settings. The Hawthorne Studies, and especially their popular interpretation by Elton Mayo, a vigorous crusader against the boredom of factory jobs, made the case for the importance of considering the human element in the workplace. The focus of industrial/organizational (I/O) psychology was broadened from *industrial efficiency* and productivity to include human relations and employee satisfaction as key variables. Through the 1960s and 1970s there was a major push for job enrichment. Somewhat earlier, researchers at the Tavistock Institute had laid the foundation for the sociotechnical systems approach to the design of work. With its use of open-system thinking and its emphasis on the multiskilled self-directed work team as the fundamental unit of work, the sociotechnical approach stood against Taylorism, and it captured in an embryonic way many of the essential elements that we now recognize as central to the high-performance organization model.

The *Japanese revolution* in manufacturing of the 1960s and 1970s dramatically highlighted another core weakness of the mechanistic model. Assembly-line workers who performed a narrow range of repetitive tasks typically did not know whether they were producing a quality product. When Japanese manufactured products suddenly came onto the world market, they were noted for their outstanding quality. Several quality techniques that are integral to the modern high-performance organization were popularized by the Japanese revolution: quality circles, statistical process control, total quality management, six sigma, just-in-time inventory management (*Kanban*), continuous improvement (*Kaizen*), and lean production, to name but a few.

The environment of business is marked by change. Huge environmental shifts—such as the growth of technology, the globalization of the economy, the changing demographics of the workforce, changing customer demands, increased competition, and the tightening regulatory environment—have pressed organizations to rethink their underlying assumptions, and their organizational structures and systems, to position themselves for success in the midst of such *turbulence*. The traditional bureaucratic organization model was not built for flexibility and does not fit a turbulent marketplace.

To achieve and sustain high levels of business performance and *quality of work life* (QWL) for

employees in the highly competitive and rapidly changing marketplace, organizations have increasingly moved away from the bureaucratic structure of the past and embraced a series of practices, which collectively define the high-performance organization. The high-performance approach is intended to be comprehensive and superordinate; application of subcomponents (e.g., process reengineering, customer-supplier partnerships, work cells) in a piecemeal way is seen as a partial and incomplete *solution* to the complex problem of sustaining organizational excellence in a turbulent environment.

Although there does not appear to be a consensus on a single, comprehensive definition of the high-performance organization, the research and practice literature point to a set of common elements, many of which are visible in benchmark organizations:

- *Teams*: Perhaps the most visible and pervasive marker of the high-performance model is the widespread application of the team concept. Production is commonly done by small *semiautonomous* teams, which set production schedules, manage quality for themselves, do equipment maintenance, and solve problems as they arise. Through open information sharing, teams understand the business sufficiently well that they do not need to call on a supervisor or other resources to address their daily issues. Such self-directed work teams are usually multiskilled, so individual jobs are enriched and teams can deploy their resources flexibly. Teams are also visible in nonproduction functions in the high-performance model as well—quality improvement teams, safety teams, new product development teams, procurement teams, and recognition teams, for example.
- *Titles and roles change*: Multiskilled employees operating in a team concept are commonly called *associates*, *technicians*, *team members*, or some other term with a professional connotation befitting their expanded role. Also, although in the past the supervisory role may have been reasonably well captured in the old definition of planning, organizing, directing, and controlling work, in the high-performance organization managers operate more as business leaders than as work bosses. They set direction for their teams (which is in alignment with the overall vision and strategic direction of their plant or unit), and they coach and facilitate more than direct or closely manage the work of others. Their roles are defined as performance manager, team builder, business leader, and change manager. Common

supervisory or management titles in the high-performance model are *team manager*, *coach*, or *facilitator*. The high-performance organization is also flatter than a traditionally structured organization, because of broadening individual job responsibilities at all levels and reduction in layers of management.

- *Employee involvement, participation, and empowerment*: Employee input and involvement on a whole range of organizational issues, leading to more empowered workers who can run their business, is central to the model. In union settings, the use of joint team structures is common; so the union participates in a leadership partnership with management, for the benefit of the business and the employees.
- *Focus on the market and customers*: In general the high-performance organization has an external focus, not just an internal focus. Workers at all levels are exposed to more real-market information than before. Employees are expected to think and act like they own the business. In some organizations teams literally run their own *minibusiness*.
- *Vision driven*: The high-performance organization focuses on creating vision, mission, and values statements, and using those broad commitments to provide overall alignment and direction to the organization. Leadership works to ensure that internal activities are aligned with each other, and with the overall vision, mission, and strategy of the business, to minimize so-called non-value-added work.
- *Innovative human resources (HR) practices*: Employees may be involved in the hiring process. Pay and incentive systems that reward teamwork and productivity—such as pay for knowledge and gainsharing—are often present. There is a heightened focus on training, not only in technical skills, but also in team skills (communication, feedback, conflict management) and business administrative skills (safety management, productivity record keeping). Indeed, the contemporary term *learning organization* is commonly applied to the high-performance organization.
- *Innovative production practices*. The high-performance organization is not a social experiment in job enrichment or the social aspects of sociotechnical systems work design. Process improvement and linkage of work to customers' needs are central to the high-performance organization. Contemporary production-improvement practices such as process reengineering, lean manufacturing, and six sigma are common.
- *Flexibility and adaptability*. The model rests squarely on the assumption that the environment of

business will continue to be turbulent and that success comes to organizations that are nimble, and can quickly and flexibly reconfigure themselves and redeploy their resources to take advantage of opportunities and avoid threats in the marketplace. Sooner or later, environmental conditions change to the point that no rigid structure will be adaptive.

The high-performance literature, spanning pop-management books to rigorous research studies, is enormous. A strong correlation between the adoption of the high-performance organization model and excellent business performance is widely reported. Anecdotally, organizations commonly claim dramatic improvements in both business performance measures (productivity, quality, cycle time) and measures of QWL (direct or indirect). Meaningful research points in the same direction, with many measures of business performance and QWL correlating significantly with the adoption of high-performance practices. Further, there is strong evidence that integrated comprehensive high-performance systems do in fact yield better results than elements implemented singly or in nonintegrated ways. Growth in the application of high-performance practices is forecast to continue.

HISTORY OF INDUSTRIAL/ ORGANIZATIONAL PSYCHOLOGY IN EUROPE AND THE UNITED KINGDOM

This article is about the history of work and organizational (W/O) psychology, as it is called in Europe; it is also known as industrial/organizational (I/O) psychology in the United States. To correctly interpret this historical account of W/O psychology in Europe, it should be taken into account that our discipline had and has different names, depending on the authors and countries. For example, the following names were used as synonyms: industrial psychology, occupational psychology, personnel psychology, work psychology, organizational psychology, psychotechnics, employment psychology, ergology, and even applied psychology. This article offers a chronological summary of the European *milestones* in the creation and consolidation of W/O psychology as a scientific discipline. In this sense I will arbitrarily divide the history into three periods: 1900 to 1945, 1946 to 1980, and from 1981 to the present.

THE EARLY YEARS AND THE DEVELOPMENT OF PSYCHOTECHNICS: 1900–1945

It is frequently stated that the German psychologist Hugo Münsterberg is the founding father of industrial, work, and organizational psychology. In effect, Münsterberg's studies on the selection of drivers and his program for industrial psychology and psychotechnics were first described by him in 1910 and 1911 when he lectured as an exchange professor at the University of Berlin. In 1912 Münsterberg published a book in Leipzig, Germany, titled *Psychologie und Wirtschaftsleben: Ein Beitrag zur angewandten Experimental-Psychologie*, which was subsequently translated into English with the title of *Psychology and Industrial Efficiency* and first published in Boston, Massachusetts, in 1913. His points of view were subsequently developed in his book *Grundzüge der psychotechnik*, which appeared in 1914. However, the work by William Stern on individual differences formed the basis of the main ideas of Münsterberg's industrial psychology. Furthermore, in several European countries some years before Münsterberg

began his experiments on personnel selection, researchers had begun to conduct personnel examinations. For example, beginning in 1901 the psychologist Ugo Pizzoli carried out professional examinations of the apprentices in Modena, Italy. In France between 1905 and 1908, Jean Marie Lahy gave the first steps toward producing a job analysis method and carried out preliminary experiments on the selection of streetcar operators. Studies on work fatigue, work curves, professional work, aptitude for working, and training were done by a variety of researchers. In 1907 the *Zeitschrift für angewandte Psychologie*, edited by Otto Lipmann and William Stern, appeared in Germany; it was the first journal in the world devoted to the applications of psychology, among them, the application of the knowledge of work problems. Stern was also the creator of the term *psychotechnics*. In summary, a complete program for work and organizational psychology has been operating in many European countries since 1907.

Regarding the use of psychological procedures for examining men, Jean Marie Lahy began to use cognitive tests for selecting drivers in France in 1908; Walter Moede, Curt Piorkowski, Otto Lipmann, and William Stern used similar tests in Germany beginning in 1914; Agostino Gemelli used psychological measures for selecting military pilots during World War I (the European War) in Italy; Emilio Mira used attention and perceptual tests for selecting drivers in Spain starting in 1918; and Cyril Burt and the members of the National Institute of Industrial Psychology (e.g., Winefried Spielrein, G. Miles) and the members of the National Board of Health (e.g., Eric Farmer) began developing and using many cognitive tests in the United Kingdom in 1914. Examples from other European countries could be cited. A consequence of this popularity was that many criterion validity studies were carried out during the first half of the 20th century in European countries, and they were largely used in civil and military contexts.

In 1920 the first international congress of psychotechnics was held in Geneva, Switzerland, under Eduard Claparède's presidency. Claparède was also the first president of the International Association of Psychotechnics founded this same year. Later, in 1952, the association was renamed the International Association of Applied Psychology. In this early period psychotechnics was primarily associated with the use of apparatus tests for the purpose of the assessment of individual characteristics. In the early 1920s various

European companies started selling psychotechnical testing equipment, while leading psychotechnicians tended to construct their own devices based on their own ideas regarding the psychological requirements of various vocations and the most suitable instruments for measuring them. The use of this sophisticated equipment contributed significantly to the reputation of psychotechnics as a solid and scientific enterprise. In the early years of psychotechnics, the most well-known psychotechnicians considered their primary task to be the development of instruments that would enable them to assess vocational aptitude as precisely as possible.

A good example of the advances in psychotechnics is the proposal by the German applied psychologist Otto Lipmann, who suggested in 1922 that occupations varied according to their cognitive demands and provided a scheme for classifying jobs. Lipmann's proposal was popular in Europe during the 1920s and was well-known by the American industrial psychologists of that age. According to Lipmann, occupations differ not solely in the mental functions they require but also in the different intensity with which specific mental functions are used. Therefore, Lipmann suggested that occupations be classified based on the nature of the object on which the work is done; and consequently, occupations could be distinguished into three groups depending on whether the action is applied to things, people, or concepts (ideas). Examples of occupations based on things could be carpentry or watchmaking. Professions involving people could be medicine or law. Finally, occupations involving concepts could be philosophy or mathematics. The Spanish psychologist Mira expanded on this classification by incorporating the relation between these dimensions and cognitive abilities. Thus, according to Mira, things are related to spatial intelligence, people are related to verbal intelligence, and concepts are related to abstract intelligence.

During the first 40 years as a scientific discipline in Europe, most W/O work was done in the areas of personnel selection, accidents, fatigue, and other areas. In 1929 Arthur Kornhauser, a pioneer American industrial psychologist, compared the industrial psychology in England, Germany, and the United States. He concluded with regard to England that he observed progress in the adaptation and application of efficiency engineering and the physiology and psychology of industrial work; but he noted little emphasis on the psychology of business management and an

acceptance of a *fixed* status of working men. With regard to Germany, Kornhauser maintained that German W/O psychology (*Industrial Psychotechnik* as it was called in that time) also showed progress in efficiency engineering, in developing psychotechnical institutes and training methods, and a deep interest in the social aspects of industrial psychology. After his review Kornhauser concluded that American *superiority* in I/O psychology was little more than an accident of natural wealth and rapid industrial growth and that the United States was nothing short of *retarded* in psychological matters.

W/O PSYCHOLOGY IN POSTWAR EUROPE: 1946–1980

The history of European W/O psychology over the next 35 years is a bit different from the previous period. Although during the between-wars period German applied psychology was the leading psychology, after World War II American research was dominant; and its influence has marked, to some extent, the situation of European W/O psychology. Thus the statistical model for personnel selection was followed and many local studies were conducted in various European countries regarding the validity of psychological procedures for personnel selection. For example, during World War II a remarkable amount of research was carried out in Great Britain on the criterion validity of intelligence and cognitive tests for predicting job performance and training success. Simultaneously, important methodological advances were made in those years in the United Kingdom. For example, Cyril Burt developed formulas for correcting for range restriction in the criterion, a kind of range restriction frequently missed in applied settings. Also, Burt and Lawley independently developed formulas for the multivariate range restriction correction. Similarly, in other European countries a considerable volume of research was carried out in the 1940s and 1950s. For example, in France, a substantial program of research was conducted by R. Bonnardel and members of the Institut d'Oriation Professionnelle. In Spain, Pinillos and other members of the Instituto Nacional de Psicotecnia carried out many validity studies. Another remarkable contribution was made in the United Kingdom when the Civil Service Selection Board, based on the 1949 work reported by Philip Vernon and John Parry, adopted the assessment

methods developed by the War Office Selection Boards; and cognitive tests, interviews, and assessment centers were used for hiring personnel. In the period between 1946 and 1970, personnel selection was probably the major activity of work and organizational psychologists in European countries.

Although personnel selection was the dominant activity, studies on organizational psychology started to appear in various European countries in this period. For example, relevant advances were made by the members of the Tavistock Institute of Human Relations in London (United Kingdom). Elliot Jaques, who developed the foundations of organizational change based on the Lewinian action-research paradigm, deserves special mention. Another advance of the Tavistock Institute was the development of the concept of organizations as sociotechnical systems. These pioneer studies were conducted in the years preceding the application of this knowledge to work restructuring and to the conduction of experiments on *industrial democracy*, for example, at Phillips Industries in the Netherlands, in Norway under the auspices of the Oslo Work Research Institute, and in the Volvo company in Sweden. In the 1970s a group of psychologists and sociologists from 12 European countries carried out a study on industrial democracy in Europe. They examined the impact of formal rules for participation (laws, collective agreements, and formal managerial policies) on the factual participation behavior in 134 organizations matched according to size and technology. They found that the best single predictors of de facto participation are hierarchical level and the intensity of prescribed norms for participation. Other relevant studies were made by the Aston group (Great Britain), who studied the effects of organizational variables on individual behavior and their relationship with their environment.

RECENT CONTRIBUTIONS OF EUROPEAN W/O PSYCHOLOGY SINCE 1980

In the last 25 years, European W/O psychology has made some relevant contributions to the knowledge of human behavior at work both in the professional area and in research advances. A first professional contribution to the field was made by a group of 35 professors of W/O psychology from 15 European countries, who founded the European Network of Organizational and Work Psychology (ENOP) in 1981; ENOP's objective was to develop a model of the curriculum for the training of work and organizational psychologists in Europe. A

second relevant professional contribution took place in 1991, when the organization European Work and Organizational Psychology (EAWOP) was founded with the mission of promoting and supporting the development and application of W/O psychology in Europe and facilitating links between scientists and practitioners working in the field across Europe. Subsequently, EAWOP founded the *European Journal of Work and Organizational Psychology* (EJWOP) in 1992.

Regarding research, in the last 15 years various European integrative studies or quantitative meta-analyses have been published; this represents a significant contribution to our understanding of relationships between individual variables and subsequent measures of job performance and other organizational criteria. For example, Ivan Robertson and Silvia Downs examined the validity of work sample tests of trainability in 1989. Jesús Salgado examined the validity of the Big Five in the European Community in 1997. Salgado's studies showed that conscientiousness and emotional stability were valid predictors for all occupational groups, and it generalized validity across samples and criteria. His findings also showed that conscientiousness and agreeableness were predictors of counterproductive behaviors (i.e., deviant behaviors at work) and that the five dimensions predicted turnover. More recently, he found that job complexity is a relevant validity moderator of personality measures and that the magnitude of validity coefficients was much larger than was previously thought. The validity of cognitive abilities for predicting job performance and training proficiency was also examined in the European context. A European team of researchers led by Salgado and Anderson examined the magnitude of the validity of the cognitive measures in six European countries and across the European Union; and they found that general mental ability is the best single predictor of job performance and training success (Salgado & Anderson, 2003).

In this last period, European research has also made a relevant contribution to the study of deviant behaviors in the workplace. This contribution refers to the topic of *mobbing* or *bullying*; and it was first described in 1984 by Heinz Leymann in a report published by the National Board of Occupational Safety and Health in Stockholm, Sweden. The term *mobbing* is typically used in the Nordic countries (Norway, Sweden, Denmark, and Finland), Germany, the Netherlands, France, Italy, and Spain, whereas *bullying* is used in English-speaking countries. Furthermore,

two special issues of the *European Journal of Work and Organizational Psychology* (Zapf & Leymann, 1996; Zapf & Einarsen, 2001) were devoted to the theme.

In this last period Europe has also contributed to the discipline with several international reviews and journals. Examples of the journals and reviews published in Europe are the *International Journal of Selection and Assessment*, *Journal of Occupational and Organisational Psychology*, *Applied Psychology: An International Journal*, *Journal of Organizational Psychology*, *European Journal of Work and Organizational Psychology*, *International Review of Industrial and Organizational Psychology Series*, *Le Travail Humain*, and *European Review of Applied Psychology*, together with national journals in Belgium, the Netherlands, Germany, Spain, Italy, and other countries.

SUMMARY

Since its origin in the early 20th century, W/O psychology has benefited from the contributions of European researchers in the field. In the first decades, European psychologists pioneered many advances in the knowledge of human behavior at work and they practically established the discipline as it is currently known. It could be said that W/O psychology was European in its origin. Among the most relevant contributions to cite are the creation of the psychotechnic laboratories in many European countries and many apparatuses for assessing human aptitudes important for work, the development of the first paper-and-pencil tests for assessing intelligence, the development of methods for job analysis, the study of fatigue at work, and the learning curves. The European W/O psychologists conducted hundreds of local studies for estimating the validity of different personnel selection procedures, and German and British psychologists may be considered the creators of the assessment center method, now widely used across the world. The European W/O psychologists are also responsible for many contributions at the organizational level—such as the Tavistock Institute studies, the studies on industrial democracy and the participation of workers, and the studies of the Aston group on the effects of the environment on organization. More recently, they have contributed by conducting meta-analytic reviews on the prediction of job performance and other organizational criteria through individual difference variables;

and they also contributed to the examination of the deviant workplace behavior known as mobbing or bullying.

Today, European work and organizational psychology enjoys remarkable success, as is demonstrated by the number of journals published on the Continent, the presence of European researchers on the editorial boards of non-European W/O psychology journals, and the international conferences in this area, and by the many studies conducted in Europe that are cited by colleagues from other countries and taken as models for the advance of W/O psychology as a science.

HISTORY OF INDUSTRIAL/ ORGANIZATIONAL PSYCHOLOGY IN NORTH AMERICA

The confluence of dynamic external (socioeconomic, business, military, legal, technology) and internal forces (individuals, theories, research, applications)

transformed the science and practice of industrial/organizational (I/O) psychology from the foresights of a few individuals into a legitimate scientific and applied discipline. Throughout the evolution, an underlying theme persisted: The study and use of psychology for improving the workplace and work lives. As early as 1913 Hugo Münsterberg advocated that the purpose of a new applied psychology was to connect laboratory science with the problems of business.

THE ROOTS: LATE 19TH CENTURY

The birth of an applied psychology, then labeled business psychology, economic psychology, or industrial psychology, was linked to the inception of psychology as a scientific discipline at the end of the 19th century. Thus I/O psychology has its roots in experimental psychology, the study of individual differences or differential psychology, and psychometrics. Wilhelm Wundt, in his German laboratory, used the experimental method to control observations for studying objectively mind and behavior to distinguish psychology from philosophy. Two graduates of Wundt's doctoral program, James McKeen Cattell and Münsterberg, relocated to the United States and initiated the application of psychology to solve industry problems. Unlike Wundt, who was interested in general laws of behavior, Cattell measured individual differences and introduced the mental test. He was first located at the University of Pennsylvania and then Columbia University. Münsterberg headed the psychological laboratories at Harvard University in 1892. Also during this time, Francis Galton coined the term *co-relation*, and Karl Pearson discovered the mathematics behind calculating the correlation coefficient. The American Psychological Association (APA) was founded in 1892 to formalize psychology as a discipline.

THE BEGINNING: EARLY 20TH CENTURY

Psychologists were compelled to legitimize their science by demonstrating the value of psychology to society because of institutional pressures and society's images of psychology as common sense or as occultism and superstition. A great emphasis was placed on empirical methods, which resulted in various measurement methods (mental tests, observations, and case studies) and statistics for measuring and analyzing individual differences (regression, simple correlation,

and partial correlation). Meanwhile, an American functional psychology called *functionalism* was formulated, which challenged the pervading structuralism view in psychology because it emphasized *how* and *why* the mind adapts the individual to its environment rather than focusing solely on the structure, or *what*, of the mind. This functional perspective provided a foundation for applying psychology.

The primary business objectives during the late 19th and early 20th centuries were to improve efficiency, increase productivity, and decrease costs through standardization and simplification. Scientific management experts Frederick Taylor and Frank and Lillian Gilbreth addressed these objectives by investigating and designing work to improve efficiency. Through the use of time and motion studies, a precedent was established for scientists to enter organizations. In 1915 Lillian Gilbreth was the first individual to complete a doctoral dissertation on the application of psychology to the work of classroom teachers.

A focus on productivity influenced business leaders to determine strategies for advertising, selling, and distributing their goods. In 1901 young psychologist Walter Dill Scott gave a presentation about the value of psychology for advertising to the Agate Club, a group of business leaders in Chicago, and then published his ideas in a book, *The Theory of Advertising*, in 1903. In 1913 Münsterberg published *Psychology and Industrial Efficiency*, the first major text on applied psychology.

In 1915 Walter VanDyke Bingham directed the Division of Applied Psychology at Carnegie Institute of Technology (CIT) to create opportunities for research, applications, and collaborative efforts with industry. Bingham hired W. D. Scott in 1916 to lead the Bureau of Salesmanship Research. Scott was also appointed professor of applied psychology, the first appointment by that title in academia. Bingham, Scott, and colleagues developed methods for selecting and training sales personnel (e.g., personal history blank, interview, reference form, mental alertness tests). Later, the bureau was renamed the Bureau of Personnel Research.

In the beginning the objective of an industrial psychology was to improve organizational goals (productivity and efficiency) primarily by applying psychology with an emphasis on individual differences, through selection and training. For example, in 1910 Münsterberg developed an aptitude test for streetcar operators. Most applied psychologists were

employed at universities; the first full-time psychologist in industry on record was Henry Link, director of training and psychological research at the Winchester Repeating Arms Company, in 1917. The same year the current premier scientific journal, *Journal of Applied Psychology*, was created.

WORLD WAR I: 1917–1919

When the United States entered the war in 1917, Robert M. Yerkes (then president of APA) and other psychologists formed a committee to evaluate a psychological examining program for recruits. Simultaneously, Scott and Bingham formed the Committee on Classification and Personnel to aid the Army in the selection of officers. These psychologists collaborated in developing intelligence tests to be administered to groups, known as the Army Alpha and Army Beta group mental ability tests. These tests paved the way for large-scale intelligence testing and for later expansion of psychological testing into government, industry, and education.

AFTER WORLD WAR I: THE 1920s AND 1930s

Forward-looking managers and organization leaders sought the use of psychological applications, techniques, and programs developed for the Army. Scott and his colleagues of the Army's Committee on Classification and Personnel formed the Scott Company in 1919, the first I/O private consulting firm. The consultants used mental ability group tests, job standards, performance ratings, and oral trade tests. The CIT expanded its work to include investigating vocational interests and developing sales training, with the establishment of the Research Bureau of Retail Training. The Carnegie program awarded the first PhD in industrial psychology to Bruce V. Moore in 1921 and was instrumental in preparing several applied psychologists, especially women. Also in 1921 Cattell organized the Psychological Corporation, which consisted of 20 influential psychologists as directors and approximately 170 psychologists holding stock. The organization's purpose was to advance and promote applied psychology.

During the 1920s, the emphasis was on the use of mental ability tests to select proficient employees or employment testing, until around 1930. In addition, the concepts of validity and criterion were introduced, and analysis of variance (ANOVA) was developed, the

graphic rating scale for performance appraisal was published, and the measurement of attitudes was improved by the scaling techniques of L. L. Thurstone in 1927, and later Rensis Likert in 1932. A widely published research program known as the Hawthorne Studies was conducted at the Hawthorne Works of the Bell System's Western Electric Company in Cicero, Illinois. The original purpose of the study was to examine the relationship between illumination levels and productivity. Researchers observed that workers changed their behaviors regardless of the illumination levels. Results revealed that work groups and attitudes had an effect on performance and that workers' behaviors changed because they were being watched, which has become known as the Hawthorne Effect. These studies are frequently regarded as the basis for a human relations movement in I/O psychology.

An emphasis on employee welfare during the depression led to development of personnel counseling as a popular organizational intervention for helping employees solve problems. Other developments in the 1930s included the 1932 publication of the first modern I/O psychology textbook by Morris Viteles, the formulation of work motivation theories, attempts to measure job satisfaction, introduction of factor analysis, and the 1937 establishment of the American Association of Applied Psychology (AAP) Section D: Industrial and Business Psychology, an early professional organization for psychologists in industry. The U.S. Employment Service developed the General Aptitude Test Battery (GATB) and completed the first large-scale systematic analysis of jobs, the *Dictionary of Occupational Titles* (DOT), in 1939. This project moved psychologists toward realizing the importance of matching individuals with job requirements.

WORLD WAR II

World War II brought new challenges and psychologists were ready to respond. Significant developments included the Army General Classification Test (AGCT), situational stress tests, and the selection and simulation training of pilots to fly warplanes. The U.S. Office of Strategic Services (OSS) developed the assessment center as a technique for selecting spies and sabotage agents. One of the first comprehensive applied psychology programs was the Aviation Psychology Program directed by John Flanagan. World War II served as an impetus and was a turning point for leadership research.

BEYOND WORLD WAR II: 1940s AND 1950s

After the war the economy provided prosperity, affluence, education, and a heightened awareness of the good life. An explosion of psychological applications and research opportunities occurred, especially in commercial testing. The focus was on fitting people for jobs and fitting jobs for people. Other areas included job analysis and job evaluation, salaries and wages, placement, promotions, training, performance appraisal, job satisfaction and morale, counseling and guidance, labor relations, industrial hygiene, accidents and safety, equipment design, and quality circles. The forced choice rating system for evaluating performance was introduced during the 1940s. Work motivation theories were further developed and leadership research projects such as, the Ohio State Leadership studies ensued.

The economic and political division of the world along capitalist–communist lines, the emergence of the Soviet Union as a superpower, and the threat of nuclear war increased military spending. Several military research centers were created, such as the Navy Personnel Research and Development Center (NPRDC) and the Air Force Human Resources Laboratory (AFHRL). Psychological research organizations were created (American Institutes for Research, for example); consulting firms were established, such as Richardson, Bellows, Henry, & Company; and research groups were formed in private corporations including General Electric and Standard Oil of New Jersey. For example, a research group at the American Telephone and Telegraph Company (AT&T) was created in 1956 to conduct a longitudinal study to discover qualities related to managerial success and advancement in the company. Universities also organized research centers to investigate aspects of work. In 1944 Kurt Lewin established the Research Center for Group Dynamics at the Massachusetts Institute of Technology, where he collaborated with a similar group in London, the Tavistock Institute of Human Relations. The establishment of numerous graduate programs further legitimized I/O psychology as a discipline.

In 1945 the AAAP merged with the APA to form APA Division 14, Industrial and Business Psychology. Several division members and others began meeting separately in a group called Psychologists Full-Time in Industry to discuss pertinent topics. Additional informal groups were established in the 1950s—such as

the Dearborn Conference Group and the No-Name Group—with the purpose of facilitating communication and interaction to advance the science and practice of I/O psychology.

By the end of the 1940s, the discipline of I/O psychology had dramatically evolved. Viteles revised the title of his 1932 book in 1953 to *Motivation and Morale in Industry* because of numerous changes, including more complex theories of motivation, and attention to emotions and attitudes, such as job satisfaction. Edwin E. Ghiselli and C. W. Brown published a major text, *Personnel and Industrial Psychology*, in 1948, which became the key reference in I/O training and education. Modern cognitive psychology began in the 1950s, which led to significant developments in years to come. One survey revealed at least 1,000 psychologists who were employed full-time in industry in the United States in 1959.

THE 1960s AND 1970s

Unrest surfaced in American society because of changes in values and enhanced attention to discriminatory and unfair practices, the Vietnam War, baby boomers in the workforce, and international and foreign competition. The civil rights movement had begun in the 1950s when the separate-but-equal doctrine in education was struck down in the case of *Brown v. Topeka Board of Education* (1954). The Civil Rights Act (CRA) of 1964, Title VII, prohibited discrimination in employment because of race, color, religion, sex, or national origin. This and other legislation, such as the Age Discrimination in Employment Act of 1967, significantly influenced I/O developments in fair employment practices and test validation. The development of guidelines for doctoral training in industrial psychology in 1965 further legitimized the discipline of I/O psychology.

A new generation of employees questioned the authority of organizations, which stimulated interest in democracy and autonomy in the workplace. These changing societal views, along with flagging productivity, forced organizations to rethink their ways of dealing with and managing employees. North American companies changed from highly bureaucratic authoritarian structures to open systems, emphasizing total quality management, teamwork, and employee participation. How the organization could best serve the individual became important. Research was stimulated in areas of communication, conflict management,

socialization, organizational climate and culture, and group development and maturation. The creation of interventions for facilitating organizational development (OD) surfaced.

During the 1970s several Supreme Court decisions, including *Griggs v. Duke Power Co.* (1971), further highlighted the need for job analysis and test validation to defend tools and techniques used for personnel decisions. The federal government developed administrative guidelines for employment selection procedures, which included definitions of adverse impact and employment discrimination. Validity generalization and meta-analysis were introduced as approaches for generalizing validity studies across various jobs and organizations. Cognitive-based theories began to emerge, especially in the areas of motivation and leadership. In 1976 a one-volume *Handbook of Industrial and Organizational Psychology* was published by Marvin Dunnette.

Because of the changing nature of the field, APA Division 14, *Industrial and Business Psychology*, changed its name in 1973 to better reflect the discipline's science and practice. *Organizational* was added to the name to become Division 14, *Industrial and Organizational Psychology*. Other developments included the establishment of consulting firms such as Development Dimensions International and the Center for Creative Leadership; the implementation of teams in business and industry; and the formulation of social learning theory, which influenced training approaches and conceptualizations of work motivation.

1980s AND BEYOND

In the 1980s stagnant productivity and threats to economic well-being heightened concerns about productivity and quality. Serious attention was given to utility analysis, and a renewed interest in organizational development built relations between organizations and employees. With the fall of Communism and the passage of the North American Free Trade Agreement (NAFTA), a global and diverse workforce became commonplace. Other changes included increased competition, restructuring, mergers, and acquisitions. The Americans With Disabilities Act in 1990 created an emphasis on identifying essential job functions, physical requirements, and job design. The CRA of 1964 was amended by the CRA of 1991 to prohibit quota hiring, which renewed interest in fair personnel decisions.

In 1982 APA Division 14 incorporated as the Society for Industrial and Organizational Psychology (SIOP) to achieve some independence from the APA. The overall purpose of SIOP did not significantly differ from the purpose established by the AAAP Section D in 1937. In 1988 some SIOP members elected to join the newly formed Association for Psychological Science (APS), which was established for psychologists with scientific interests.

Although military spending on research decreased during this time period, some projects were successful. In 1990 John Campbell described Project A, a large-scale project for the U.S. Army; this endeavor involved several psychologists over a 10-year period to research the selection and classification of military personnel and develop the Armed Services Vocational Aptitude Battery (ASVAB). Another example of military research was the extensive investigation of team training and performance completed by the U.S. Navy's Training Systems Center.

A plethora of developments in I/O psychology have occurred since the 1980s. These include a cognitive perspective of performance appraisals; organizational justice theory; computerized adaptive testing; personality testing for employment; Internet for recruitment, assessment, and selection; research on work stress and work-family balance; the Occupational Information Network (O*NET) to replace the DOT; and the second edition of the four-volume *Handbook of Industrial and Organizational Psychology*.

Over the years I/O psychology shifted from a simple, narrowly defined technical field focused on individual issues for accomplishing organizational objectives to a complex, broad scientific and applied discipline emphasizing individual and organizational issues for achieving both individual and organizational goals. Today the objective is to improve both organizational goals or efficiency and individual goals or efficiency by applying psychology and by theorizing and researching psychology in the workplace, with consideration for individual and organizational factors. The key challenge within the discipline is to maintain an identity as a rigorous scientific discipline, while at the same time providing a growing range of professional services and applications.

HISTORY OF INDUSTRIAL/ ORGANIZATIONAL PSYCHOLOGY IN OTHER PARTS OF THE WORLD

This entry presents the history of industrial/organizational (I/O) psychology in four countries: Israel, India, Singapore, and Australia. It points out some similarities in the evolution of the profession across diverse cultures.

ISRAEL

Early 20th Century

The presence of psychology in Israel is traced back to 1930, when a group of German-Jewish psychoanalysts fleeing persecution in Nazi Germany arrived in Israel under the leadership of Sigmund Freud's student Max Eitingon. In 1933, they established the Palestine Psychoanalytic Society.

Post-World War II

The establishment of the state of Israel in 1948 has accelerated the need for psychologists in the areas of clinical, educational, vocational, industrial, and military psychology. In the first three years of the State of Israel, the population grew from about 600,000 to 1.7 million people; and it is up to about 6,800,000 today. The number of people in the civilian labor force rose in 2004 by 2.6% compared with the previous year and reached 2.678 million. According to the Central Bureau of Statistics, the percentage of people in the labor force reached 54.9% in 2004.

Vocational psychologists and industrial psychologists helped develop the new civilian labor force.

Military psychologists and industrial psychologists were needed mainly for selecting soldiers and officers and placing them into their new roles in the Israel Defense Forces (IDF).

In 1947 Louis Guttman founded the behavioral unit of the military, which eventually became the Israel Institute of Applied Social Research. His research contributions to the theory and practice of scale and factor analysis, multidimensional scaling analysis, and facet theory have made a significant impact on the fields of social, military, and industrial psychology.

Attempts to establish a department of psychology in Israel began in the 1930s; but they were actualized only in 1957 when the first department of psychology in Israel was founded at the Hebrew University, headed by Professor Shlomo Kugelmass, an immigrant from the United States who emphasized experimental psychology.

In the same year, the Israel Psychological Association (IPA) was established, with divisions in clinical psychology; educational psychology; and later on a division of social, occupational, and industrial psychology. Since its inception with 170 members, the association has grown up. Today there are 3,500 members with 280 members in the division of industrial psychology.

Additional departments of psychology, with graduate level programs in industrial psychology, were established at Bar-Ilan University (1958), Tel-Aviv University (1967), and Haifa University (1967). Ben-Gurion University established a department of behavioral sciences, which includes psychological studies (1984); and the Technion established a graduate program in industrial psychology (1985).

In 1977 the Knesset, Israel's parliament, passed the *Psychologists Law*. It mandated the establishment of the Council of Psychologists in the Ministry of Health to enforce the new law's licensing procedures regulating who may practice psychology and a variety of regulations concerning professional practice.

Industrial and organizational psychologists in Israel practice in industry, in the IDF, and in private consulting firms. They are involved in numerous areas in personnel psychology, organizational behavior, and human factors. In the area of personnel psychology, Israeli industrial psychologists are responsible for establishing criteria and measures for personnel selection, assessing managerial potential, and appraising performance. Furthermore, they are involved in management development, training, and management

consulting. In the area of organizational behavior, they design and implement organizational change; advise Israeli companies on how to become global companies; develop motivational techniques for enhancing productivity; consult companies on the development and shaping of the organizational culture; run stress reduction workshops; and offer advice on decision-making processes, gender issues, organizational justice, and other important issues needed for the competitive advantage of companies today. In the area of human factors, industrial psychologists are involved in new product design, taking responsibility for the interface between employees and the technology systems. There is a great demand for graduate degrees in industrial and organizational psychology as graduates of these programs get job offers from the Israeli industrial sector, high-tech sector, service organizations, and the public and government sectors.

Research in I/O psychology reflects the needs of the country. Among these are the need to absorb, integrate, and acculturate successive waves of immigrants with diverse ethnic backgrounds; to resolve the Arab-Jewish conflict; to improve leadership, decision-making, and work motivation; to improve the interface between people and technological systems; and more recently to research on cross-cultural management, reflecting the need to integrate into the global business context.

Israeli professors of I/O psychology are highly involved with the worldwide community of I/O psychology. They serve as journal editors (*Applied Psychology: An International Review*) and associate editors (*Academy of Management Journal; Management Science*); there are also fellows of the Society for Industrial Organizational Psychology and the Academy of Management who are Israeli professors, and the past president of the division of organizational psychology at the International Association of Applied Psychology was also Israeli. The publication record of Israeli researchers in leading scientific journals is way above their proportion in the scientific community, demonstrating once again that science is universal and is shared beyond geographical borders.

INDIA

Ancient Time

The roots of psychology in India can be traced to ancient Indian religious-philosophical thought that

evolved out of Indian religion and philosophical traditions, epics, and folklore originally in the oral tradition. The large number of Indian scriptures contains references to and the analyses of mental status and contents of mental activities of human beings over millennia. These ancient expositions are mostly based on the experiences of sages, and seers, wise men and self-verification by them. There were no clear distinctions between religion, philosophy, and psychology in ancient Indian culture; the overarching consideration was to assist individuals in their pursuit of self-realization and liberation from the miseries of life. It is, however, not easy to consider this psychological knowledge as *scientific* in the strict and modern sense of the term.

Early 20th Century

Psychology as a modern and scientific field of study was first introduced in India in 1905 as a subject in the philosophy department of Calcutta University; the first course offered was in experimental psychology, along with the establishment of a psychological laboratory. In time this laboratory evolved into the first department of psychology in India at Calcutta University in 1915. This was gradually followed by the setting up of psychology departments in several other universities. Two separate departments, experimental psychology and applied psychology, were started at Patna University in 1946.

Post-World War II

The early years saw a fair amount of research and publication. A survey done in 1972 showed that 90% of the publications in all fields of psychology were dated from 1950 and after; the only exceptions are the areas of experimental and social psychology, with figures approximately 70% and 77%, respectively, because research was done in these areas beginning in 1950 (Mitra, 1972). Three areas, clinical, personality, and social psychology, accounted for 50% of published material between 1950 and 1972. Industrial psychology made its appearance in the postindependence (1947) period. The reason was the priority accorded to industrialization by the government of the newly independent country. The focus was on development of heavy industry, which had concomitant development in industrial psychology. Mitra wrote that the 1972 survey by the Indian Council of Social Science

Research indicated about 11% of all the papers published in psychology to be in industrial psychology.

The rapid industrialization of the 1950s and 1960s created the need for better understanding of the psychology of the workplace; worker, production, and organizational efficiency; and labor management relations. Areas that received attention at this time were job attitudes, work incentives, absenteeism, and job satisfaction (Ganguli, 1961). One of the major centers for psychological research was the Ahmedabad Textile Industry Research Association (ATIRA), which was established in 1950. Well-known psychologists such as Erik Erikson, David McClelland, and A. K. Rice were frequent visitors to this institute where several large-scale surveys were conducted to study psychological issues related to the textile industry. Rice did some of his pioneering work in industrial psychology in India in 1955 using the sociotechnical approach in an experimental automatic loom shed here. A survey by Durganand Sinha in 1972 showed that while only 25 studies were done in the field of industrial psychology until independence in 1947, as many as 508 studies were done from 1948 to 1969. Two major areas that accounted for the bulk of the studies were performance and job satisfaction (139 studies), and management and organization (128 studies). Other areas studied were occupational choice and guidance; selection and placement; training, task, and work analysis; special environment; advertising and consumer psychology; engineering psychology; driving and safety; and surveys and general studies. This review also noted that research in industrial psychology had an academic focus possibly because of the absence of contact between academic psychologists, the research they produced, and other organizations.

The early 1960s saw initiation of formal management education in the country with the setting up of two Indian Institutes of Management, at Ahmedabad and Calcutta, which had separate areas of study called organizational behavior and behavioral sciences, which provided the impetus for organizational psychology.

The latest survey found the focus of I/O psychology shifting to motivation, leadership, and human performance (Kanungo & Misra, 2004). Some trends toward indigenization and cross-cultural psychology were, however, discernible.

Industrial/organizational psychology in India seems to continue to evolve in keeping with the broad socioeconomic situation in the country and also staying in touch with global trends.

SINGAPORE

Singapore, with a population of more than 4 million, is an urban city-state. Eighty-five percent of Singaporeans live in public flats, of which 94% are owner occupied. The major components of Singapore's gross domestic product by industry as of 2004 were manufacturing, wholesale and retail, transport and communications, business services, other goods industries, and financial services. Singapore is therefore a setting in which I/O psychologists can make major contributions.

Industrial and organizational psychology is presently offered as an optional undergraduate third-year module in the psychology department at the National University of Singapore. There are indications from Web site listings of the Nanyang Technological University and the Singapore Management University of plans to offer the module at some future date.

The Singapore Psychological Society (SPS) has the most comprehensive data about I/O psychologists who are members of the society. It is the sole national association of psychologists in Singapore.

According to the membership data as reported by the then SPS membership chair, the I/O SPS members reported their areas of specialization and highest academic qualifications as follows: seven members with doctorates in ergonomics (4), occupational (2), and I/O psychology (1); nine members with master's degrees in occupational (5) and I/O psychology (4); and one postgraduate in I/O psychology.

The membership strength of SPS at that time was 247, out of which 159 had postgraduate qualifications. The I/O psychologists therefore represented 10.7% of the SPS members with postgraduate qualifications.

Although only 17 psychologists with postgraduate qualifications identified themselves as I/O or occupational psychologists and ergonomists, a total of 47 full members of the SPS indicated that they were engaged in work settings that typically engage I/O psychologists. Such work settings include work with the police (6%), military (21%), and commercial (23%) organizations. The highest percentage (47%) worked as consultants, whereas one (2%) was affiliated with a bank.

One inference that may be drawn from this disparity is that at least 64% (30 out of 47) of the psychologists working in these traditionally I/O work settings do not have postgraduate qualifications. As some of the postgraduate I/O psychologists are with academic

establishments, a better estimate of the percentage working outside academia without postgraduate qualifications is more than 70%. Approximately 28% of the I/O psychologists work for the public sector. The private sector, composed of commercial establishments, consultancies, and a bank, make up the remaining 72%. The demand for I/O psychology in Singapore is therefore predominantly in the private sector.

The Singapore workforce has had to face the challenges posed by a downturn in the economy since the late 1990s. *The Business Times, Singapore*, reported on August 24, 1998, that 14 electronic firms had retrenched 4,800 workers in the first half of the year.

The Business Times, Singapore also reported, on April 7, 2004, that the Singapore workforce, which had regularly earned accolades in the 1980s and early 1990s by country risk consultancies (e.g., BERI [Business Environment Risk Intelligence]) for being among the world's most productive, was now encountering stiff competition to maintain its position.

In the process of structural transformations in the country, widespread workforce educational upgrading and skills retraining programs, and calls by the political leadership to change mind-sets toward perceived low-status jobs, there is much that I/O psychologists can do. However, there needs to be set in place a process for the training of sufficient numbers of I/O psychologists to meet this need. Arguably, this could best be achieved by planning and implementing a full-fledged academic program to train I/O psychologists in one of the tertiary institutions in Singapore.

AUSTRALIA

Industrial/organizational psychology has been an active part of Australian psychology throughout its history and has begun to diversify in the late 20th and early 21st centuries. At many points since its inception, the story of Australian I/O can be linked to major developments in the United States and Britain; but there are also interesting differences that we highlight, together with key milestones.

EARLY 20TH CENTURY

At the beginning of the 20th century, a close relationship existed between philosophy and psychology.

Henry Tasman Lovell was appointed to the first officially titled post in psychology in the philosophy department at the University of Sydney in 1910. Elton Mayo was appointed the first chair of philosophy at the University of Queensland in 1910. By 1913 most Australian universities were teaching mental philosophy or an equivalent. The close link between philosophy and psychology in universities remained for quite some time, substantially longer than in the United States and Britain.

POST-WORLD WAR I

Elton Mayo and Bernard Muscio warrant specific mention during this period. Their legacy can be traced to issues in current I/O psychology, but Mayo's name is the most immediately recognizable because of his work at Harvard and the Hawthorne Studies. The psychological and medical treatment of returning veterans was a focus for Mayo's work in the postwar period. This work led to a series of papers concerning the state of consciousness termed *revery* and its relevance for managers and workers in industrial society. Elton Mayo is credited with a major role in the human relations movement, which included his views on industrial society and the role managers should play in industry.

Bernard Muscio was appointed the Challis Professor of Philosophy at the University of Sydney in 1922, and the development of the field of industrial psychology throughout the British Empire is credited to him. Like Mayo, he published a number of papers during the early 1920s on fatigue and related topics in industry.

In 1927 Alfred Martin at the University of Sydney established the Australian Institute of Industrial Psychology (AIIP). The primary industrial applications of psychology were directed toward vocational guidance and testing, spurred on by the establishment of a Vocational Guidance Bureau in New South Wales in 1926. By 1969 the Commonwealth Department of Labour and National Service employed 60 psychologists, and most worked in vocational guidance.

Psychological testing was more closely associated with education than industry. Australia's first psychological laboratory, which first was established at the Melbourne Teachers College in 1903 and later closed, reopened in 1923. The Australian Council for Educational Research (ACER) began conducting psychological research in 1930.

POST-WORLD WAR II TO 1970

As in other countries, in Australia, World War II involved psychologists in a variety of activities to support the armed forces and broader society. In 1940 Martin brought together the Volunteer Emergency Psychology Service comprising the AIIP, the education department, and the Vocational Guidance Service (later known as the Vocational Guidance Bureau), and educational institutions. The Australian Council for Educational Research was involved in testing of military personnel.

Overall, Australian management was more reluctant than its U.S. and British counterparts to use industrial psychologists. In the decades following World War II, the application of testing was relatively limited and the focus of personnel activities remained vocational guidance and welfare.

LATE 20TH CENTURY

In the 1970s several social psychologists became associated with organizational psychology, reflecting similar development in the emergent field of organizational behavior in the United States, where some of the Australian scholars such as Gordon O'Brien were trained. Norman Feather, a colleague of O'Brien's at Flinders University, was another social psychologist whose writings became influential in motivational theories within organizational behavior.

In the 1990s a third stream of research started with the arrival or return to Australia of many organizational psychologists who had been trained at or otherwise associated with the Institute for Work Psychology at Sheffield University. These scholars are spread around the country; and their research addresses issues in the work design, teams, and organizational performance areas. Much of this work is now blending with that of organizational behavior researchers, whose work is focused on a wide range of areas, including motivation and emotions, negotiation, careers, and cross-cultural and other topics. The individual differences tradition, which has the longest history of the three streams, continues in studies of human resources systems. As in the United States, individual differences are more likely to be taught in psychology departments, whereas organizational behavior and work design topics are more frequently taught in schools of management and business.

There are many Australian researchers who are prominent scholars of international standing, but there

is no distinctive Australian research approach or set of issues. In the last part of the 20th and the beginning of the 21st centuries, there has been increased funding available in Australia for applied research conducted in collaboration with industry. Organizational psychologists have been among the more successful groups in the award of these grants. Thus there is the potential for an Australian set of issues and perspectives to emerge.

The Australian Psychological Society established the Board of Organizational Psychologists in 1972, and at this writing it has more than 14,000 members. There are research and professional streams in most of Australia's 38 universities. Australian psychologists are well represented in the management of universities and professional bodies.

HONESTY TESTING

See INTEGRITY TESTING

HUMAN-COMPUTER INTERACTION

Human-computer interaction (HCI) is a concept addressing a variety of aspects in the interaction between humans and computers. These aspects include how a user commands the computer; how the computer presents information to the users and performs their commands; and how this interaction begins, proceeds, and ends. On a broader scope, HCI is often viewed as the multidisciplinary domain dealing with all aspects of the study, design, evaluation, and deployment of interactive computer systems.

COMPUTER APPLICATIONS IN EVERYDAY LIFE

Computers are everywhere. We find the computer in life-critical systems such as traffic light control systems or the airport control tower. Many of the medical systems, imaging, diagnostic, and treatment, are computer driven. And at any workplace, be it the office or the factory, we find computerized systems: from word processing and accounting, through architectural or printed circuit board (PCB) design or newspaper typesetting, up to computer numerical control (CNC) machine control and material conveyance. Even at home we have computer games and Internet browsing. Our wristwatch, cellular phone, and personal digital assistants (PDAs) all are computers. Our interaction with computers has become a fact of life.

INTERACTION IS ACHIEVED VIA THE USER INTERFACE

The *user interface* is the medium between the user and the computer that enables the interaction between them. The user interface consists of three basic components:

1. **Controls:** The controls are usually objects that enable giving commands to the system. These could

be buttons, knobs, menus, sliders, voice commands, keyboards, and many more.

2. **Displays:** The displays are both the information conveyed to the user as part of the interaction and also the medium that conveys the information. These could be screens and monitors, sound, graphs and visualizations, text and narrative, printouts, and much more.
3. **Interactions or Dialogs:** The combination of giving commands and instructions to the computer, on one hand, and displaying information by the computer, on the other hand, merges together to become the dialog between the user and the computer.

HISTORICAL PERSPECTIVE: FROM CHARACTER-BASED TO GRAPHICAL USER INTERFACE

In the beginning interaction with computers was achieved by using mediums such as punched card readers and magnetic tapes. Computing and processing were executed *behind the scenes* (batch work fashion) and the output to the user was printed. In other words, there was no direct communication or dialog between the user and the computer.

The concept of interaction appeared early in the 1960s. This concept referred to the dialog between human and computer, similar to human-to-human dialog. Interaction required technological progress such as the ability of the computer to *speak* with a number of users simultaneously (time sharing) and perform the processing for them during the interaction (real-time processing). There was also a need to develop the interaction channels and replace the punched cards and the printed output with something else.

Indeed, several technological developments in the computer world brought us closer to an interactive user interface. These developments included visual display units such as a cathode ray tube (CRT). The development of the displays started with presenting only characters to fully graphic displays showing pictures, drawings, and a variety of colors. The computer's processing units were developed in a way that enabled time sharing and real-time processing. The interaction channels included the appearance of the first mouse in 1965, use of a light pen that points on the screen, and a transfer to the digitizing tablet. In the 1970s many technological developments occurred that made a huge step toward the user interface as we know it today. These developments included the first

personal computer by Xerox; and later Apple appeared and in 1977 presented its first personal computer.

The personal computer infrastructure enabled the development and appearance of the graphical user interface (GUI). Xerox was the pioneer and in 1981 introduced the Xerox Star, the first personal computer with a GUI. In this interface the main familiar elements of a GUI were introduced: windows, icons on the screen, desktop metaphor, and other principals that will be outlined later in the text. The Star computer was a commercial failure, but Apple turned the GUI into the popular and dominant HCI channel with a computer called Lisa and later with the Macintosh. Microsoft followed and added the Windows environment on its operating system, which dominates a significant portion of the personal computing domain.

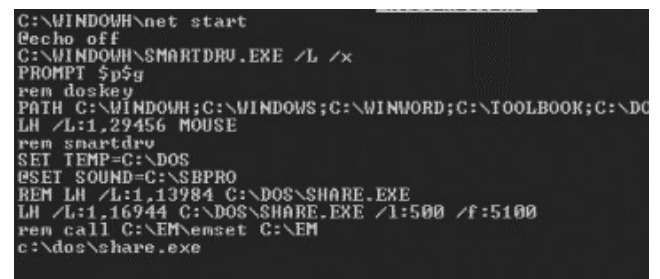

Until recent developments in display technology, the user interface was character based (Figure 1).

This interface limited the amount of information that could be displayed. For example, in personal computer screens, this amount was limited to 24 rows with up to 80 characters in each. In addition, each character had a fixed size and shape. This interface dictated limited operating modes such as command language dialogs (different dialog forms will be discussed in the following text). The GUI was developed with the development of visual display technology. This technology provided almost unlimited color display, high resolution details, fast response time of the display, ability to use large screens, and more.

This interface has several features that are familiar today to every computer user. The features are detailed as follows.

WYSIWYG: What You See Is What You Get

This feature means that what the user sees on the screen represents exactly the way the information will

```

C:\WINDOWH\net start
@echo off
C:\WINDOWH\SMARTDRV.EXE /L /x
PROMPT $p$g

LH /L:1,16944 C:\DOS\SHARE.EXE /I:500 /f:5100
rem call C:\EM\nset C:\EM
c:\dos\share.exe
  
```

Figure 1 Character-Based User Interface

look when printed. This feature is possible because of the advanced display technology consisting of high-resolution display elements, the pixels. It is important to note that even contemporary display technologies do not match the print resolution, but the display is a good approximation of the output.

This feature can save a lot of time in the user’s work. Instead of wasting valuable time in repeated trials and errors of printing until the exact desired output is achieved, it is possible to make interactive attempts on the screen.

Windows, Icons, Mouse, and Pull-Down Menus (WIMP)

As mentioned earlier, the use of windows was one of the first and most significant features of the GUI. The window enabled the display of several different items simultaneously—such as documents, drawings and sketches, and data—and the ability to move among them easily and quickly.

The use of a mouse as a pointing device was advanced significantly with the emergence of the GUI. There is the capability to use the mouse with character-based displays; however, it lacks the strong and intuitive association between the continuous movement of the hand moving the mouse and the respective visible movement of the cursor on the screen. The high-resolution graphic display enabled a continuous and smooth movement of the cursor on the screen in perfect correlation with the location, direction, and rate of the hand movement with the mouse.

Pull-down menus were also one of the control mechanisms in non-GUI interfaces. However, GUIs provided a number of menus simultaneously, using the menu bar, which is usually at the top part of the window, for immediate access to many actions. This feature contributes significantly to increasing the efficiency of work with the system.

The use of icons to represent objects and actions is a significant element of a graphical interface (Figure 2).

Graphic Metaphors and Visual Language

High resolution and a variety of colors enabled almost anything to be shown in pictorial fashion. Today, applications, objects such as documents or drawings, and actions are all visually represented by icons. Icons appear as a way to initiate programs, select an object,

Figure 2 Example of GUI Interface With Icons and Menu Bars

Figure 3 Example of a Graphic User Interface

and launch various operations. The icons have an advantage over using words because it is easy to identify them quickly, they are not dependent on using technical or unknown terminology, and they add to the aesthetics of the user interface (Figure 3).

To present the available options and commands, on the one hand, and the information that is presented by the system, on the other hand, a graphical language is used. It is taken either from everyday life or from a domain known to the user. For example, Figure 3 shows a user interface for playing music on the computer that looks exactly like a real recording system. This way the user has almost nothing to learn to be able to use the system.

Object Oriented

Most of the computer’s elements and the variety of applications for it are represented as objects on the screen: disk drive, network communication, trash can for deleting, or a type of a document. This way of

displaying is familiar and intuitive to users from everyday life, and it enables the users to see and understand immediately what they can work with and what they can do. The fact that the object is displayed and accessible enables one to first select it and then choose a certain action to apply on the selected object.

Direct Manipulation

Together, all the characteristics that were mentioned in the previous text enable an interaction method that is intuitive to people. Instead of typing commands and selecting things indirectly, the ability to move the cursor in a totally random way on the screen and select objects and launch actions directly suits the way people do things in daily life. The direct manipulation principle consists two of main characteristics of the user's work:

- Point and click
- Drag and drop

For example, to copy a document to a different directory, the user points at the document, selects it (usually using the button on the mouse), *drags* it over the screen, and drops it into the target directory.

EXAMPLES FOR USER-COMPUTER DIALOGS OR INTERACTION STYLES

Command Language

This dialog is based on typing commands to the computer in a specific language. The best-known example is the command language of the Microsoft Disk Operating System (MS-DOS) for personal computers or the questions language called standard query language (SQL) of large databases. This way of interaction requires learning a language: vocabulary, grammar, and syntax.

Application: Command language as an interaction mode is appropriate for experienced and expert users, in cases where expenses on learning time are not a critical factor and for tasks that require fast operation time and flexibility in giving commands.

Questions and Answers

This approach is like a session of questions and answers between the user and the computer. Questions

are presented to the user, who selects one answer from several that are offered. The computer executes the action based on the answer or asks another question, and so on, until all the information and parameters required for completing the operation are given.

Application: This approach is appropriate for novice users or tasks that can be defined in a single track, where the progression is from one phase to the next. This approach is common for tasks such as installing hardware or software where it is important to ensure that all the steps are taken in the correct sequence.

Menu Selection

This dialog is based on displaying a list of items, objects, or actions; and the user selects an item to activate or perform various operations. Menu selection is an old interaction approach that was prevalent also in character-based interfaces. In the past, selecting the item was done mostly by typing the option number in the menu or some shortcut (a functional key or the first letter of the option, etc.). In the GUI era selecting the option is done by directly pointing on the desired item.

Application: Menu selection, being a structured interaction approach, is appropriate for novice or infrequent users. It is also suitable for tasks where speed is not a critical factor for successfully completing the task.

Form Filling

This dialog approach is based on data entry required to complete a given task. Usually, the data is displayed as a form; and the user navigates within the form using either the keyboard, by skipping from one field to another, or in direct access with the mouse and filling in the necessary data. In graphical interfaces data can be entered in various ways, from typing it into an input field to using different controls (as check boxes, radio buttons, combo boxes, or spinners for numbers). Dialog boxes are the forms in GUIs.

Application: Form filling interaction is appropriate in applications where there is a need to update parameters in a fluent and efficient way during a task.

Direct Manipulation

This dialog approach, as mentioned earlier, is the most common and typical GUI. Because of the nature of the graphical interface, objects and actions are displayed in a unified and consistent metaphoric frame (like the desktop metaphor), and the user executes actions in a direct way in this framework. In this way there is no need for typing commands or selecting from menus. The basic operations in the direct manipulation approach are the point and click on an object or command, and the drag and drop, which help to manipulate entities.

Application: Using this dialog approach is applicable mostly to nonverbal tasks with spatial characteristics such as drawing or painting. It can be appropriate for both novice and expert users.

OBJECTIVES IN THE DESIGN OF A GOOD HCI

Easy and Short Learning

The user interface should shorten the learning time for using the system. The learning duration has a direct influence on user attitude toward the system: A system that is simple to learn to use will be perceived as comfortable and easy to use. In addition, the duration of learning has an influence on the deployment and system usage costs. With a lower learning cost, the added value of the system increases because the time for starting the production is shorter.

Efficiency

It is not enough that the user can perform the job with the computer. Performing the job has to be efficient: saving time with an accurate and quality product. If work with the system is slowed down because the user has to look in the user guide to perform any given operation or the number of operations required to complete a task is too large, less value is added by using a computer.

Minimum Errors

Errors can occur during the user's work with the computer. They can result from human errors or from problems and failures in the computer system itself.

A good interface will be evaluated according to the way it deals with errors. It should show error detection and display the appropriate information to the user about the error and its characteristics. In addition, it should let the user handle the error. The interface has to be forgiving of user mistakes. If errors will be destructive and irreversible, the user will be discouraged from using the system. Poor error handling mechanisms will affect the learning process of the system and the efficiency of working with it.

Satisfaction

A short and easy learning process, the ability to work efficiently with the system, and the ability to handle errors in a nondestructive way all bring the user satisfaction with his work with the system. This satisfaction is essential to the successful deployment of the system and to effective work with it. The subjective satisfaction of the user is influenced also from the aesthetic aspects of the user interface. Although beauty is subjective, a good interface complies with basic aesthetic rules, as well as employing other approaches that make work with the system pleasant and even fun.

HCI: SOME CONTEMPORARY EMERGING CHALLENGES

Information Visualization: The graphical depiction of large amounts of information in ways that integrate and synthesize the information, and let the user interact with it according to their objectives and tasks.

Computer Supported Collaborative Work and Computer Mediated Communication: The use of computers to support and mediate collaborative work and communication between people.

Mobile Computing: The implementation of a variety of applications and programs in mobile devices such as the cellular phone or the PDA.

Virtual Reality: The simulation of environments in an immersive fashion such that the user perceives and feels as if he or she is actually *inside* the simulated environment. Used primarily for training and games.

HUMAN FACTORS

See ENGINEERING PSYCHOLOGY

HUMAN RELATIONS MOVEMENT

Viewing the Hawthorne Studies as the linchpin that connected scientific management to new thinking and practice, the human relations movement is the result. This entry approaches the human relations movement from three vantage points:

1. Genesis and growth of the movement
2. Key concepts and practices of the human relations movement
3. Role of the movement in shaping the history and trajectory of industrial/organizational (I/O) psychology

Further readings are provided at the end of this entry. The entry clarifies that researching investigators, practicing consultants, and working managers contributed to the human relations movement.

GENESIS AND GROWTH

Two early figures, related through the Hawthorne Studies and Harvard Business School, were Fritz J. Roethlisberger and G. Elton Mayo. Roethlisberger was a Harvard Business School professor for 40 years; Mayo was a Harvard professor with training in psychopathology. The human relations movement emerged through their writings, in opposition to scientific management. The various members of the movement, without excessive formal identification, promulgated an attitude toward organizations that emphasized persons, groups, and relationships.

The human relations movement began with impetus from the findings of the Hawthorne Studies that both group norms and worker attitudes are important and account for variance that is left unaccounted for by scientific management and personnel selection. The movement began during the period spanning the irrational zest of the late 1920s and the start of the Great Depression. The shift was documented in the titles of two books by Morris Viteles. Specifically, the revision of *Industrial Psychology* (1932) illustrated the evolution of the field when it appeared as *Motivation and Morale in Industry* (1953). Even as industrial psychologists continued to develop personnel testing techniques, documented by Harold Burt in 1926 and 1929 and then by Morris Viteles in the magisterial *Industrial Psychology*, the roots of organizational psychology were being cultivated in the study of attitudes and groups. Another individual who made the transition to a focus on job attitudes and mental health of the worker as well as industrial conflict, from an early focus on testing aspects of industrial psychology, was Arthur Kornhauser. Several individuals went undercover to write popular accounts of how workers thought and behaved. Satisfaction became an important outcome for the human relations movement. Researchers developed job satisfaction surveys following unobtrusive investigations during the 1920s (for example, Whiting Williams, *Mainsprings of Men*), and the Hawthorne researches provided guidance on personnel interviewing and counseling. Context and environment were important to workers, and thus to management, and eventually to I/O psychologists.

Two other individuals were important in advancing models of cooperation, paired with productive conflict, as a preferred organization for business firms. Mary Parker Follett, trained in political science, presented analyses of power relationships within

organizations that have been rediscovered by the I/O field. Chester Barnard, a CEO of New Jersey Bell Telephone who was also influenced by Harvard Business School faculty, wrote about management in *Functions of the Executive* (1938). He discussed the directives of supervisors and the varying acceptance by subordinates. Chester Barnard developed concepts of strategic planning and the acceptance theory of authority. Strategic planning is the formulation of major plans or strategies, which guide the organization in pursuit of major objectives. Barnard believed that the prime functions of executives were to establish effective communication systems, hire and retain effective personnel, and motivate personnel. These functions vary from standard treatments in their inclusion of communication systems as an important facet of the executive position.

Moving on through the interval between 1950 and 1970, Douglas McGregor and Rensis Likert stand out among others in terms of their influence on the human relations movement. McGregor proposed theory X and theory Y views of workers held by managers at multiple levels of organizations from supervisors to executives. Simplifying, theory X pertains to a scientific management perspective, whereas theory Y pertains to a human relations perspective. It is of interest that many organizations and managers continue with theory X perspectives and may suggest a contingency interpretation. Rensis Likert influenced them in several ways: They included his early work on scaling and later work on conducting surveys to support World War II efforts, as well as his role in founding the Institute for Social Research (ISR) at the University of Michigan. Likert identified systems of exploitive, benevolent, consultative, and participative management and worked with colleagues at the ISR to develop diagnostic tools and planned change interventions. A major vector of influence was Kurt Lewin. The influence was transmitted through Lewin's emphasis on groups and lifespaces but perhaps to a greater extent through his training of many social psychologists who studied within organizations.

KEY CONCEPTS AND PRACTICES OF THE HUMAN RELATIONS MOVEMENT

The human relations movement is known neither as a formal school nor for a single set of practices, whether considering the System 1–4 framework of Rensis

Likert or the acceptance theory of management by Chester Barnard. Assessing, understanding, and working with employee attitudes were its hallmarks, however, and contributed to the formation of organizational psychology, as noted by Harold Leavitt. Training for supervisors in human relations was also prominent during the interval between 1940 and 1966, as indicated by a search of the historical research database. The effectiveness data were of course meager. The emphasis of the human relations movement on the study of groups and organizations meant that theory and research moved away from a myopic preoccupation with the individual level of analysis to a more integrative conception of micro-, meso-, and macroinfluences and consequences of behavior.

ROLE OF THE HUMAN RELATIONS MOVEMENT

Arthur Bedaeian and Daniel Wren, based on an order of merit ranking procedure, placed multiple books from the human relations movement in their list of the top 20 books in management during the 20th century. Two important effects of the human relations movement were the development of the organizational branch of I/O psychology (and organizational science, broadly defined) and the emergence of professional development for managers. The organizational branch of I/O psychology is concerned with groups and norms, attitudes, motivations, interests and values, and roles. Remembering ability in general or training to influence worker capabilities, the human relations movement enhanced our suite of potential causes of observed behavior and advanced job design and redesign as another class of action levers. It also demonstrated application links with other areas of psychology, for example using the scaling procedures of Thurstone and of Likert to measure job attitudes. Systematic studies of and interventions around labor–management relations were another offshoot of this movement seen in organizational psychology, as are current concerns with forms of job affect and withdrawal and interventions to influence them. Professional development for managers, whether T-group work at the National Training Laboratories (NTL) or role-playing of interviewing and communications with subordinates or participation in large-scale networked simulations, is a large and booming business. All these tendrils, and more, are offshoots of the human relations movement.

HUMAN RESOURCE MANAGEMENT

Human resource management (HRM) refers to the design of formal programs to enhance the effective and efficient use of employees to achieve organizational goals. In essence, it is the *people practices* and ranges from hiring new employees to developing them into successful organizational members to managing their separation from the company. Human resource (HR) professionals administer these programs and can be generalists or specialists. Generalists have some knowledge about each HR function (i.e., jack-of-all trades), while specialists are experts in one particular function such as recruitment, labor relations, or training.

PURPOSES OF HRM

Traditionally, the primary purpose of HRM has been administrative, which includes designing and administering programs, such as recruiting, training, performance evaluations, payroll, and benefits. A second purpose of HRM is being an employee advocate. Human resource professionals need to voice employee

concerns and protect their rights by acting as liaisons. Third, HRM must serve as a change agent by helping organizations adapt to the constantly changing business environment. For example, HR professionals can enact family-friendly policies in response to the increased number of women in the workforce. Finally and most important, HRM should be strategic by aligning all HR functions with organizational goals. For example, if a company's mission includes providing excellent customer service, HR professionals must hire and train workers with good customer service skills, provide feedback on customer interactions, and reward those displaying superior service.

HRM FUNCTIONS

The field of HRM covers many functions, which are briefly described in the following text:

Equal employment opportunity laws prohibit discrimination against applicants and current employees based on their demographic characteristics—such as race, gender, religion, national origin, age, and disability—in all terms and conditions of employment. Human resource professionals must ensure that all employment decisions are based on merit or other nondiscriminatory reasons.

Job analysis is the process of describing the essential tasks, duties, knowledge, skills, and abilities needed to successfully perform a job. The outcome of this process is a job description that can be used to determine what skills applicants need, what type of training should be conducted, what to evaluate employees on, and so forth.

Human resource planning entails forecasting the number of employees who will be needed (demand) and the availability of workers (supply) as well as creating programs to remedy any mismatch between demand and supply. To resolve an employee shortage, HR professionals can recruit new employees, hire temporary workers, outsource, require overtime, or reduce turnover. Likewise, when there is a surplus HR can conduct layoffs, implement job sharing, reduce work hours or pay, or transfer workers.

Recruitment involves identifying and attracting a large pool of applicants for a job. Internal recruitment is hiring from within organizations by identifying internal job candidates through performance evaluations, job postings, or manager recommendations. Conversely, external recruitment seeks candidates from outside organizations through newspaper ads, Internet job boards, employment agencies, college career centers, job fairs, or word of mouth.

Selection refers to matching job candidates to the appropriate job. In other words, it involves hiring the most qualified people in the hope that they will successfully perform the job. Many methods are used to identify the best candidates—including applications, résumés, interviews, assessment centers, background checks, and tests such as cognitive (intelligence) or physical ability, personality, and integrity.

Orientation programs introduce new employees to the organization, job, and individuals within the company. These programs typically discuss company history and mission, policies, procedures, pay, and benefits.

Training provides employees with the knowledge and skills needed to perform their jobs. Training can be conducted on the job where employees learn as they go, often while supervised by a manager or senior employee. It can also be off the job where employees learn away from the actual work setting using classroom lectures, videos, role-playing, simulations, or computer-based training.

Performance appraisal is the process of observing, evaluating, giving feedback, developing, and rewarding job performance. Typically, supervisors evaluate performance, but 360-degree feedback in which multiple raters (supervisors, subordinates, coworkers, customers, and self) evaluate performance is gaining popularity. Performance can be rated based on results such as number of sales or behaviors including teamwork, as well as in comparison to coworkers or predetermined standards.

Compensation and benefits are used to attract and retain employees. Compensation is monetary payments employees receive from their employer and can include base pay, cost-of-living adjustments, and merit or incentive pay. Benefits are a form of indirect compensation that may be required by law—including workers' compensation, unemployment insurance, or unpaid family and medical leave—or voluntarily offered by companies—such as paid leave, retirement or pension plans, child care, educational assistance, or medical insurance.

Health and safety programs protect employees' psychological and physical well-being. Employee health can be enhanced through wellness—including exercise facilities, health screenings, or educational programs—or employee assistance programs that help manage personal problems such as substance abuse and stress. The Occupational Safety and Health Act (OSHA) of 1970 requires that organizations provide a workplace that is free from recognized hazards. Compliance can be achieved through safety programs that include safety policies, training, protective equipment, and inspections.

Labor relations are important because organizations are required by law to recognize and bargain in good faith with unions. Human resource professionals can participate in collective bargaining, facilitate union-management relations, and ensure that management does not engage in unfair labor practices, such as threatening to fire employees who vote for a union.

Employee relations cultivate relationships that balance employer needs and employee rights regarding issues such as electronic communication monitoring, drug testing, and termination. Management should be accountable for upholding these rights, and employees abusing them should be disciplined according to company policy.

SOCIETY FOR HUMAN RESOURCE MANAGEMENT AND HR CERTIFICATION

The Society for Human Resource Management (SHRM) was established in 1948 and represents more than 190,000 HR professionals. It strives to advance the profession by providing resources, networking, and professional development. SHRM also advocates the key role HR professionals can play in formulating and implementing organizational strategy. SHRM founded the Human Resource Certification Institute, which offers three types of HR certification. First, the *professional in human resources* is for those with less HR experience and jobs that are technical or operational. Individuals with more HR experience and jobs that are strategic or policy oriented can attain the *senior professional in human resources*. Finally, HR professionals operating in multinational organizations can receive the *global professional in human resources*. To become certified, individuals need at least two years of HR experience and must pass an exam covering the field of HRM.

HUMAN RESOURCES STRATEGY

Human resources strategy focuses on two primary issues:

1. The degree to which human resources (HR) practices are aligned with business strategies
2. The extent to which these practices influence organizational performance

It is also based on three key assumptions:

1. Human resources can be a source of competitive advantage.
2. Human resource practices have a direct influence on the motivation and productivity of organizational members.
3. Such practices are key determinants of organizational performance.

Although strategies for managing people in organizations have been the focus of research in management and industrial and organizational (I/O) psychology since the turn of the century (e.g., Scientific Management, Likert's Systems-4 Management), there has been a renewed interest in the topic in recent years. Furthermore, researchers have offered several new frameworks for understanding the effects of HR practices on organizational performance including the best practices model, the alignment model, and the resources-based model. These models and research examining their effectiveness are described in the following text.

THE BEST PRACTICES MODEL

One framework for understanding strategic human resources management has been labeled the best practices model. This approach argues that there are sets of best practices in the field of HR management, and

the use of these practices has a positive influence on organizational performance or profitability. Some empirical research conducted in a variety of countries, such as the United States, Japan, Israel, and Korea, supports this prediction. For example, research has indicated that the use of high-performance work practices—including job analysis, training, employment testing, quality of work life programs, and incentive compensation—is positively related to firm performance and profitability. Similarly, research comparing production lines in the United States and Japan found that Japanese production lines were more productive than U.S. lines. However, the productivity rates of U.S. lines were equal to the Japanese lines when Japanese management systems were used. Although most research has found that high-performance work practices are positively related to an organization's profitability, results of one recent study found that these work practices increase productivity but also increase labor costs.

THE ALIGNMENT MODEL

Another framework for understanding HR strategy has been characterized as the alignment model. This approach suggests the effectiveness of organizations can be increased if HR practices are aligned with the competitive strategies used by organizations to differentiate themselves in the marketplace. For example, firms that differentiate themselves based on cost or speed use different HR practices than those that seek to gain a competitive advantage based on quality or innovation. Some empirical research has shown that organizations following different business strategies use different HR practices, and studies have shown that manufacturing and financial performance is enhanced when firms align their HR practices with the firm's business strategy.

THE RESOURCE-BASED MODEL

Still a third model of strategic human resources management has been designated as the resource-based model. This model emphasizes that human resources can be a source of competitive advantage for organizations, but the value of people is not always readily apparent. In addition, the resource-based model contends that human resources may be a key advantage in organizations because they provide organizations with a unique pool of talent that is not easily imitated or

substitutable. Furthermore, this model suggests that a combination of HR practices may be more difficult to imitate, and therefore, more valuable to the organization than a single practice—such as use of valid selection techniques. A number of empirical studies have provided support for this prediction and found that bundles of HR practices are more effective than individual practices. In addition, research suggests that HR practices need to be synergistic or complement one another if they are to have an impact on organizational performance. Similarly, research has revealed that firms often have higher levels of performance when they use different HR practices for different employee groups rather than use a uniform HR system with all employees. Similarly, research has indicated there are often sets of critical employees in organizations who are responsible for the organization's core competencies, and retention of these individuals is a key determinant of the success of organizations.

MEDIATING FACTORS

Although some research has shown that sets of HR practices may be related to organizational performance, researchers argue that it is important to understand the processes that mediate this relationship. As a result, research in strategic human resources management has examined the extent to which productivity, voluntary turnover, and organizational flexibility mediate the relationship between high-performance work practices and organizational outcomes, including

profitability and return on investment. In addition, researchers have argued that HR systems create clearly defined social structures, and strong systems clarify organizational goals and the nature of the exchange between employees and employers. Finally, researchers contend that HR practices affect firm performance because they increase employee skill levels, motivation, and perceptions of empowerment. Although this argument seems highly plausible, little empirical research has directly examined the degree to which these psychological factors mediate the relationship between HR practices and organizational performance.

I

IMPLICIT THEORY OF LEADERSHIP

What is leadership? Is it leaders' behavior or our image of it? For example, if you are a female manager, how often has an outsider taken you for your own secretary? How often does that happen to your male colleague? This is what research on implicit leadership theories (ILT) focuses on. What are our ideas of what a leader is like (e.g., male, as further explored later in this paragraph)? Whereas prior leadership research has studied the leader and his or her behavior, scholars studying ILT have taken a different approach. According to ILT scholars, the *actual* behavior or characteristics of the leader are less important for finding out what leadership is than our particular *ideas* about what leaders are and what characteristics or behaviors they should exhibit. It has become clear that individuals are well able to produce ideas about leaders in general, ideal leaders, effective leaders, and so on, without referring to an actual leader they know. When meeting a person labeled *leader*, this image of a leader in general is activated. To illustrate: Imagine you are at a party and your friend tells you that she is going to introduce you to a friend of hers who is a top leader of a Fortune 100 company. Immediately, you will have an idea about this person's attributes. For example, you might imagine this person to be male, dominant, intelligent, and so on. These characteristics do not come out of the blue. Virginia Schein has found that we often imagine leaders to be male, and recent research on the contents of our implicit leadership theories has found that

characteristics such as dominant and intelligent are often named as typical for leaders.

Similarly, not only do we have ideas about leaders before or when we meet them, but, as the Robert Lord research group found, we also tend to label a person a leader who fits our ideas of a leader. This means that we are well able to say whom we believe to be the leader of a group we are observing. But we would be wise to be cautious: We can, of course, be mistaken. Leaders who do not possess "typical" leader characteristics may often mistakenly be seen as subordinates.

According to Robert Lord and colleagues, the implicit theories of leadership that are stored in our minds are often associated with the idea of success. When individuals observe a group and are given information concerning the performance of that group, they tend to remember more leadership behavior when told that the group was successful than when told the group was not successful. Remember, we are talking about different observations of exactly the same behavior, simply owing to differing information concerning group success.

Interestingly, this is a tendency we can also find on a broader societal level. James Meindl and colleagues examined newspaper articles and found that particular emphasis was put on the leader of a specific company in times when companies performed well and in times when they performed poorly. We all know this phenomenon from our daily lives: Just think about how often sports coaches are made responsible for the failure and success of their team and are, in times of failure, consequently replaced.

WHAT EFFECTS DO IMPLICIT LEADERSHIP THEORIES HAVE?

What consequences does the knowledge that people have ideas about leaders have for organizations and their leaders? Judith Nye has focused on the idea that a match between followers' implicit leadership theories and their leaders' behavior may have an impact on the evaluation of their leaders. Nye and her colleagues found that once followers have ideas about leaders that do not fit their leader's actual behavior, their evaluation of their leader will be less positive. This is of course important for leaders to know, as it can have an impact on their effectiveness with these followers. In addition, we have seen in leadership research that different followers may see the same leader in different ways. Implicit leadership theories can help us understand this fact. Birgit Schyns, Jörg Felfe, and colleagues undertook research on the perception of leadership and found that implicit leadership theories influence the perception of leadership. This means that implicit leadership theories, or the ideas we have about what leaders are like, affect what we see in our own leaders. This, then, can explain why one follower may see, in effect, a different leader than another follower sees. Taking into account how often followers are asked to rate their leaders, for example in the context of 360-degree feedback, the impact of such an effect should not be overlooked. Tiffany Keller reports another critical finding, namely that the match between the implicit leadership theory of an employee and his or her actual leader predicts job satisfaction.

ARE IMPLICIT LEADERSHIP THEORIES GENERALIZABLE?

In our world of diversity, intercultural cooperation, mergers, and expatriates, it is important to be aware of the differences in implicit leadership theories that exist among different members of the workforce as well as in different cultures. Laura Graves and Gary Powell found evidence that men and women differ in their implicit leadership theories. We also know from research by David Day and Charlotte Gerstner that students with different cultural backgrounds have different implicit leadership theories. The Global Leadership and Organizational Behavioral Effectiveness (GLOBE) research project undertook a cross-cultural examination of implicit leadership theories about effective leaders in 62 cultures. This group

found that some of the attributes associated with charismatic leadership are considered indicators of effective leadership across different cultures, but the importance of other characteristics of effective leadership are different in different countries.

This research indicates that leaders working in different cultures may be confronted with followers who have different ideas about how leaders are and how they should be. This influences the expectations followers have concerning their leaders and, in turn, will probably affect their evaluation of these leaders and influence the amount of effort they are willing to exert to support them. Imagine, for example, an individualistic leader acting in a collectivist country. Strategies can be extremely successful in one country yet can trigger misunderstandings and even repudiation in another country. We can imagine that the idea of a leader in a collectivist country is more dominantly shaped by an emphasis on group identity than on individual achievements. So, because of such different implicit leadership theories, leaders may have different effects in different countries.

SUMMARY AND CONCLUSION

We have seen in this short overview that implicit leadership theories exist, which is to say that people have particular beliefs concerning leaders even before they encounter a leader and that they apply these beliefs to a person labeled *leader*. We have also seen that these theories develop early and are different for male and female individuals, as well as for individuals with different cultural backgrounds. In addition, this overview shows the consequences of implicit leadership theories for organizations. The following related issues have begun to be discussed only very recently.

THE FUTURE OF IMPLICIT LEADERSHIP THEORIES

Recently, the concept of implicit leadership theories has been broadened. In 2005, Reinout de Vries and Jean-Louis van Gelder introduced the term *implicit followership theories*, arguing that people not only have ideas about how leaders are, but also about how followers are. In a similar direction, Mary Uhl-Bien has argued that individuals have *implicit relationship theories*. These theories affect the cooperation between, for example, leader and follower, as both enter the relationship with different or similar ideas

about what such a relationship should look like. Brigitte Kroon introduced the idea of *implicit organizational theories*. Her line of argumentation has considered how these implicit organizational theories affect the start-up of a company—that is, how they shape our image of companies, as well as how actual companies are shaped by the idea of its founders.

These examples show how implicit theories in general, and implicit leadership theories specifically, have an impact on leaders, members, and organizations in general.

IMPRESSION MANAGEMENT

Many companies use scores from personality tests when evaluating job applicants. Meta-analytic evidence suggests that scores from well-developed personality tests are predictive of job performance and other organizationally relevant outcomes, with the strongest findings observed across settings for the trait of conscientiousness. A potentially important issue

with many personality tests, however, is the accuracy of responses provided by applicants. The assumption is that applicants will respond to items in a manner consistent with their behavior, producing scores that indicate their trait standing. However, for many personality items it is possible for applicants to respond in a way that enhances their attractiveness to the hiring organization.

For illustrative purposes, consider the personality test item “I am rarely late for appointments” and an associated five-point Likert-type response scale that ranges from *strongly disagree* to *strongly agree*. Some individuals tend to respond to this item more toward the *strongly agree* end of the response scale in an applicant setting than when responding to the same item in a research setting or when taking the test for self-exploration. This phenomenon of changes in responses to such items across motivated (e.g., applicant) and nonmotivated settings has been referred to as *impression management*, *socially desirable responding*, *intentional distortion*, and *faking*.

Interest in the subject of intentional distortion is probably as old as interest in measuring personality through self-report methods. Although reviews of research on intentional distortion date back to 1946 and much is now known, more knowledge has led to more questions. Indeed, interest and research in this issue are as keen and perhaps as controversial as ever. Through the years, research has focused on four broad questions: (a) Can people distort self-descriptions of their personality? (b) Do applicants distort their self-descriptions? (c) What effect does intentional distortion have? (d) Are there remedies for intentional distortion?

CAN PEOPLE DISTORT (FAKE) SELF-DESCRIPTIONS OF THEIR PERSONALITY?

Research clearly demonstrates that when asked to do so, people can distort their responses in the desired direction. Laboratory studies with transparent personality items—that is, items for which the supposedly good or bad response options are readily apparent—show that the mean scores for respondents asked to describe themselves in as good a way as possible are significantly higher than the mean scores for respondents asked to describe themselves as they really are (honest responses). The differences are even greater between respondents asked to portray themselves in an undesirable way and those asked to portray themselves honestly.

DO APPLICANTS DISTORT (FAKE) THEIR SELF-DESCRIPTIONS?

Although people readily recognize answers to transparent items that enhance their self-description, whether or not real-life job applicants do enhance their self-descriptions is a separate question. Research suggests that at least some applicants do enhance their self-descriptions. Much of this research involves comparisons of job applicant and job incumbent test scores, and it is based on the assumption that job applicants are likely motivated to enhance their self-descriptions to increase their chances of being hired. Results of this research indicate that mean applicant test scores are notably higher than mean incumbent scores. Nonetheless, the size of the difference between incumbent and applicant mean scores varies depending on the particular personality characteristic, the type of job, and, undoubtedly, other factors, as well.

This research does not suggest that all applicants fake. Perhaps only 25% of job applicants enhance their self-descriptions on personality inventories consisting of transparent items. Moreover, job applicants who enhance their self-descriptions do so to different degrees. One applicant might raise her score by a couple of points on a scale, whereas another applicant might raise his score by several points, perhaps dramatically. Very little is known about the individual differences and situational factors that influence an individual's decision to distort or the amount of distortion. It is likely that people are differentially able to distort their scores. Certainly, one's true score on a characteristic influences the amount of distortion in a positive (or negative) direction. For example, an individual with an already high true score on a characteristic is simply unable to raise his or her score as much as someone whose true score is lower. Factors such as these seriously complicate the tasks of identifying those who have distorted their self-descriptions and determining the amount of the distortion.

WHAT EFFECT DOES INTENTIONAL DISTORTION HAVE?

Faking might have a number of possible effects on personality test scores and the usefulness of those scores. Some research has explored the extent to which faking affects the construct validity of personality measures. Generally, these studies have focused on factorial validity, comparing the factor structures of a personality measure across samples of honest

responders (typically incumbents) and people who have completed the measure in a motivated situation (typically applicants). It has been hypothesized that faking will increase the correlations between the scales and that a general faking factor will be observed in samples in which respondents were motivated to provide a positive self-impression. Research suggests this hypothesis is inaccurate. Evidence to date suggests that faking does not substantially change the factorial validity of personality measures.

Researchers have also investigated the effect of faking on the relationship between personality test scores and job performance (i.e., criterion-related validity). The expectation is that if scores on the test change (i.e., faked responses) but performance on the criterion (e.g., job performance) does not change, criterion-related validity will decrease. In other words, faked responses will lead to predictions of performance that are higher than would be predicted based on honest responses, and thus greater errors of prediction. Investigations into the effect of faking on criterion-related validity have provided mixed results, with some studies showing that faking has no effect on criterion-related validity and others showing a notable decrement in the correlation when faking is present. A review of these studies led Leaetta M. Hough to argue that the mixed results may arise from differences in setting or research context. That is, she showed that studies conducted in the laboratory tend to evidence a stronger impact of faking on the criterion-related validity of personality measures than those studies conducted in field settings (with actual applicants), where findings indicate a much smaller impact. Importantly, and consistent with Hough's conclusion, meta-analytic research indicates that criterion-related validities obtained in settings with real applicants for real jobs are similar to criterion-related validities obtained with real incumbents in real jobs. Thus, it would appear that intentional distortion has a minimal impact on the criterion-related validity of personality test scores.

Even though the criterion-related validity of a personality test might not be strongly influenced by faking in applicant settings, it remains possible that the quality of hiring decisions made using such tests will be adversely affected by faking. That is, for small selection ratios, the quality of selection decisions might be negatively affected to the extent that individuals who *appear* to have a high level of the trait (but who would be expected to perform in accordance with the actual trait standing) displace individuals whose test scores

are slightly lower but who actually have a high standing on the trait (and who would be expected to perform in a manner consistent with that trait standing). Some findings to date are consistent with this logic, suggesting that intentional distortion may detrimentally affect the quality of selection decisions, especially when the selection ratio is rather small. It should be noted, however, that much of this research has been conducted in laboratory settings or evaluated through simulation methods. Consistent with Hough's observation regarding the effects of faking on criterion-related validity, it is quite possible that lab and simulation studies overestimate the impact of faking on the quality of selection decisions. Moreover, not all research has reached the conclusion that faking harms the utility of personality tests. Findings from a recent simulation study by Neal Schmitt and Frederick L. Oswald suggest that removing fakers from the applicant pool changes mean levels of performance very little.

ARE THERE REMEDIES FOR INTENTIONAL DISTORTION?

Even though questions remain regarding the consequences of intentional distortion on the usefulness of applicant scores, many people assume that such distortion does degrade the validity of self-report responses for predicting later work performance. As applicant and client perceptions of fairness and validity are important, a search for and evaluation of remedies for intentional distortion is warranted.

Attempts to address issues of intentional distortion can be divided into two broad approaches. The first has been referred to as the *detection and correction* approach. The detection aspect of this approach involves the inclusion of a set of items in the personality test specifically designed to identify those individuals who may be attempting to respond in an overly desirable manner. These sets of items have been referred to as *faking scales*, *lie scales*, *unlikely virtues scales*, and *impression management scales*. The correction aspect of this approach involves adjusting scores on the various scales, often through a statistical procedure, based on scores on the impression management scale. In general, research suggests that the detection and correction approach makes little difference in terms of increasing the accuracy of individual scores or the criterion-related validity of the scores.

A second approach to dealing with faking is the prevention approach. In this approach, steps are taken to dissuade applicants from faking or to make it

difficult to intentionally raise one's scores. One prevention strategy is that of warning statements. In this strategy, a statement is included in the instructions of the test informing test takers that there are items in the test designed to identify individuals who are responding in an overly desirable manner. Meta-analytic research has demonstrated that personality test scores are notably lower when a warning statement is present in the instructions of the test. However, that benefit appears to occur only when test takers are informed that there are consequences, such as being dropped from the applicant pool, for being identified as having responded in an overly desirable manner. In other words, warnings appear to be an effective deterrent of faking only when the warning "has teeth."

A second prevention strategy involves the use of multidimensional forced-choice (MFC) item formats. An MFC item comprises two or more statements, each reflecting a different trait. The respondent must choose, rank order, or otherwise indicate preference among the statements presented in the item. Because the individual cannot make himself or herself look good on all of the statements within the item, it is thought that a respondent's capability to fake is reduced. Consistent with this line of thinking, research has shown less score inflation between motivated and nonmotivated testing situations on MFC scales than on scales with Likert-type formats. However, research also suggests that when completed under motivated testing situations, scores from MFC measures provide representations of trait standings that are no more accurate than scores from Likert-type measures. Thus, MFC formats, at least of the type that have most recently been discussed and explored, do not appear to be a remedy for faking.

SUMMARY

Personality tests are often used in personnel selection systems, and many of these tests are susceptible to socially desirable responding. Research shows that applicants can and will fake personality tests in applicant settings, although precise estimates of the percentage of applicants who fake is not well documented. The impact of faking on the criterion-related validity of personality test scores appears to be rather small, with larger effects observed in lab studies than in field studies. Likewise, studies with real applicants in real selection settings indicate the effects of intentional distortion are minimal. Lab and simulation studies suggest that faking may adversely affect the

quality of selection decisions when top-down selection is used and the percentage of the applicant pool hired is very low, although these findings need to be confirmed in field settings. Finally, with regard to remedies for faking, research suggests there are no methods that fully prevent faking or that effectively deal with the effects of faking after it has occurred. At present, the best recommendation is to include an impression management scale and warn applicants that high scores on the scale might result in their removal from the applicant pool.

INCENTIVES

In the field of human resources and compensation, *incentives* are specific rewards that are offered

contingent on the achievement of some predetermined level of performance, or the performance of some specific type of behavior viewed as desirable by the organization. It could be argued that the earliest systems of exchange between organizations and individuals were primarily incentive based (i.e., piece rate systems in which individuals were paid a fixed rate for producing a set number of units). However, with the introduction of scientific management around the beginning of the 1900s, organizations moved to paying a fixed base wage or fixed annual salary. For most jobs, with the exception of sales and some lower-level jobs, monetary incentives played a secondary role as a type of additional method of motivating desired performance beyond that offered by performance appraisal and merit raises.

For organizations today, incentives serve as a way of attempting to influence future behavior toward some behavioral or production goal. Thus, they serve as a supplement to base pay or annual salary. However, unlike the base pay a person receives, incentives can be lost as well as gained. That is, if individuals do not meet the desired level of performance, or fail to perform the desired behaviors, then they do not receive the promised reward. So, incentives differ from the pay one receives from one's job, in that incentives are directed at future behavior, whereas pay can be viewed as an exchange for past behavior. A second difference is that incentives can be lost if the behavior or performance does not occur, whereas one's base pay is guaranteed regardless of one's performance, given one works the required number of hours.

There are three general types of incentives commonly used by organizations. The first is monetary incentives. The second is nonmonetary, tangible incentives such as trips, gifts, or stock options. The third is praise or positive verbal reinforcement. Each type of incentive will be discussed briefly, primarily from the perspective of its practical application in modern organizations. This will be followed by a brief discussion of major theoretical approaches to the explanation of the effects of incentives on performance.

MONETARY INCENTIVES

A major incentive is money or pay. Most individuals receive some type of base pay in exchange for their labor. In addition to base pay, organizations may offer various types of incentive pay. This incentive pay is

often referred to as *pay-for-performance*, or *variable-based pay*.

Incentive pay is presented as a potential reward that is dependent on behavior, productivity, or the attainment of some identifiable goal. If the behavior occurs or the goal is achieved, then pay is allocated at the individual, group, or organizational level.

When pay is used as an individual incentive, behavior may be measured using objective criteria or subjective performance ratings. Behavior may also be measured, and incentives rewarded, at the team or organizational level. Such group incentive plans are often aimed at improvement in specific areas of concern to the organization, such as cost, quality, production, absenteeism, or safety. Popular schemes for allocating organizational incentives include profit sharing, gainsharing, and goal sharing.

Skill- and competency-based pay can also be considered to be types of monetary incentive systems. Skill-based pay provides rewards in the form of pay for the completion of training that results in the acquisition of various skills; competency-based plans provide rewards for the acquisition and demonstration of various behavioral competencies.

NONMONETARY INCENTIVES

Used in its broadest sense, *nonmonetary incentives* refer to pleasurable aspects of the job, benefits, and various perks. Normally, however, the pleasurable aspects of jobs and benefits are not at risk, but are fixed regardless of performance. Thus, the term *nonmonetary incentives* is used here to refer to perks such as small gifts, trips, or awards that might be offered in exchange for the attainment of specific performance goals. For example, salespeople might be offered a cruise for meeting goals for calling on potential new clients, or teachers might receive a dinner for perfect attendance.

Such nonmonetary incentives may be a particularly effective and low-cost method of motivating behavior that is not directly tied to individual production, such as absenteeism or organizational citizenship. Of course, in designing such plans, compensation professionals must carefully consider legal issues such as the tax consequences or, in the case of absenteeism, the implications of the Family Medical Leave Act.

Stock options might also be considered to be a type of nonmonetary incentive, although they clearly have monetary value. Stock options not only serve as a

reward but also impart a sense of organizational ownership.

PRAISE AS AN INCENTIVE

A special type of nonmonetary reward is praise, recognition, positive reinforcement, or affirmation. Praise is an ideal reward because it is easy to deliver in close temporal proximity to the target behavior and tends to result in positive emotional states for the recipient. It is also very inexpensive, yet very effective. In addition, as compared with financial rewards, praise can be argued to be more likely to result in increased intrinsic motivation. The effective use of praise by a supervisor can also lead to more positive perceptions of supervisor leadership and communication.

PSYCHOLOGICAL THEORIES

The concept of reward is often associated with behaviorism, and behavioral theorists have contributed a great deal to our understanding of the role of incentives in molding behavior in organizations. This has included research on reinforcement schedules, the use of praise as a reinforcer, shaping, modeling, and the use of behavior modification principles in attendance and safety interventions.

The major challenge to behaviorist theories as an explanation for the performance improvements occurring as a result of incentives is offered by goal-setting theories. According to these theories, it is the establishment and acceptance of hard but difficult goals that leads to improved performance, rather than the reward itself. Cybernetic and control-theory perspectives have expanded on the goal-setting and behavioral positions by exploring the informational and feedback role played by rewards.

EVALUATION OF INCENTIVES

It is very difficult to offer any overall evaluation of the use of incentives in organizations, in that the term *incentives* encompasses such a wide spectrum of reward options. There is a long history in psychology of research demonstrating the efficacy of both monetary and nonmonetary rewards, including praise, on behavior at the individual level. Clearly, incentives can change future behavior both through the desire for rewards and through the impact of incentives on goal setting and goal acceptance.

Incentives have also been shown to be effective in changing performance at the group or organizational level, particularly in areas such as safety and absenteeism. However, in using incentive plans for dealing with absenteeism, companies in the United States must now deal with the constraints imposed by the Family Medical Leave Act.

Monetary incentives for production or performance do appear to have an impact on retention rates. Under a monetary incentive plan, where pay is at risk, turnover tends to be lower among high-performing employees and higher among low-performing employees.

From an organizational utility perspective, the introduction of any type of incentive plan should have a positive impact on productivity and performance. However, and perhaps unfortunately, the ultimate impact of an incentive system will depend on the ability of the organization to fairly observe and measure the target behaviors.

INCREMENTAL VALIDITY

Incremental validity is a predictor's ability to explain an outcome, beyond all other predictors. For example, assume predictor A accounts for 25% of the variance in an outcome of interest and, when entered separately, predictor B also accounts for 25% of the variance. Because their influences most certainly overlap, it is also important to understand the amount of

variance each predictor explains when considered in conjunction with the other. One scenario is that predictor A and predictor B account for much of the same variance, so predictor B can be said to have low incremental validity because it adds very little new information to the prediction equation. Another scenario is that their variances overlap very little, so predictor B can be said to have high incremental validity.

Although incremental validity is conceptually simple and straightforward, it becomes difficult to estimate in practice, for several reasons. First, it is impossible to know all possible predictors of a given outcome, so it is imperative to draw from relevant, well-developed theory when defining a subset of predictors to examine. Second, the incremental validity of a given predictor necessarily fluctuates from situation to situation. For example, the incremental validity of athletic ability over intelligence is likely quite large when attempting to predict the performance of an NFL quarterback but is likely nonexistent when predicting the performance of an accountant.

ESTIMATING INCREMENTAL VALIDITY

The most widely used method of assessing incremental validity is *hierarchical multiple regression*, which allows researchers to assess the amount of variability explained by the predictors, after previous predictors have already explained their share of variance. Adding predictors to a model necessarily increases its predictive power, so an important question becomes, How do you determine when incremental validity ceases to be significant?

Arguably, the most important consideration is parsimony—that is, defining a model that is as simple as possible, without sacrificing substantial predictive power. One way to do this is by examining a model's adjusted R^2 , which indicates the proportion of variance explained in the outcome after the estimate has been slightly decreased for each predictor included in the model. This is done because adding predictors to a model *always* increases its predictive power. So, to increase the adjusted R^2 value, the incremental validity of each added predictor must outweigh its subsequent decrement in the adjusted R^2 .

APPLYING INCREMENTAL VALIDITY

Of all forms of validity (e.g., construct, criterion), incremental validity is the most applied, in that it is

typically used to better predict valued outcomes in real-world settings and often influences (and is influenced by) other considerations, such as time, money, and effort. This is especially true in the area of personnel psychology, where incremental validity is given more attention than in “purer” forms of psychology. Some have even developed *utility analyses*, which are used to translate organizational incremental validity estimates into financial savings.

One particularly prevalent application of incremental validity has been predicting applicants’ future job performance. Here, research has led to the nearly unequivocal conclusion that general mental ability (GMA, or *g*) is the best predictor of job performance across nearly all occupations. However, tests of GMA do not predict performance perfectly, so an important finding is that, under certain circumstances, predictors such as personality inventories, structured interviews, and work samples add incremental validity to the prediction of job performance.

CONCLUDING THOUGHTS

Incremental validity is a relatively straightforward concept that can cause many practical difficulties. However, many complications can be avoided by remembering that (a) incremental validity varies from situation to situation (e.g., across occupations), so one should refrain from making absolute statements about the incremental validity of any predictor; (b) there is a nearly infinite number of predictors of a given outcome, so a subset of predictors should be chosen from well-developed theory; and (c) a point of diminishing returns is typically reached after including a relatively small number of predictors, so models should be as parsimonious as possible.

INDIVIDUAL ASSESSMENT

Although individual psychological assessment is one of the most widely offered services provided by practitioners in psychology, it takes on somewhat unique characteristics in the domain of industrial and organizational psychology. These unique characteristics occur for both the assessment measurements of the individual and the outcomes that are predicted from those measurements. From a measurement perspective, the emphasis is on assessing knowledge, skills, abilities, and personal characteristics (KSAPs) that are important to functioning in the work setting. These measurements are typically different from those, for example, that would be relevant in mental health or educational settings. With respect to outcomes, individual assessment in industrial and organizational settings is most frequently concerned with selection decision making, including predicting job success/performance and antecedents thereto, such as career development or perhaps organizational fit. In fewer circumstances, it has also been used for vocational guidance and outplacement. In short, *individual psychological assessment* can be defined as the measurement of one or more components of an individual’s KSAPs to make inferences about subsequent work-related behaviors and performance.

OTHER ASSESSMENT PROCESSES

For the purpose of this discussion, the topic of individual assessment will exclude other measurement strategies that are frequently used to predict work performance, such as the preemployment interview, group testing, or assessment centers. Furthermore, the discussion is focused on the measurement of normal behavioral and psychological characteristics, as opposed to abnormal traits and behavior that might be considered in the assessment of candidates for safety-sensitive jobs (e.g., nuclear power plant operator, pilot, police officer). Finally, the individual psychological assessment is typically focused on predicting future performance rather than measuring past or current performance.

It is also important to distinguish individual assessment from other forms of evaluation that occur in organizations. Two of the more frequently used processes are performance appraisal and multirater feedback surveys. Both processes are techniques for measuring observed behaviors of individuals at work, and often there is considerable structure underlying the evaluations. Although both individual psychological assessments and the two organizational evaluation processes can be designed to measure the same constructs (e.g., performance dimensions, competencies), the perspective of the assessor/evaluator differs. Consequently, it is this independent perspective and psychological understanding (frequently supported by measurements from psychological instrumentation) that differentiates the individual assessment and provides unique information in support of selection decision making. Moreover, individual assessment is often conducted to support selection decisions during the hiring process when the organization has not had the opportunity to observe the individual at work.

ORIGINS

The origins of individual assessment have been traced to selecting individuals for government service in ancient Greece on the basis of both cognitive and physical abilities. In the United States, psychological assessment had its roots in the military with the screening of army recruits for maladjustment during World War I, and in applications by the Office of Strategic Services (OSS) during World War II. Use of individual assessments in private industry derived mostly from the early assessment centers that were designed to predict the advancement potentials of managers at AT&T in the 1960s.

DESIGN AND IMPLEMENTATION

A properly designed and implemented individual assessment follows the traditional model for the use of selection procedures as practiced in the field of industrial and organizational psychology. The design begins with a study of the job (position) of interest. The emphasis is on obtaining sufficient information about the underlying requirements (KSAPs/competencies), as well as the context (work environment), so that the assessor can determine what measurements (e.g., tests, simulations) will be administered and how the resulting information will be integrated to support

the selection decision-making process. Once the assessment protocol has been administered, scored, and interpreted, the results must be reported. The organization, of course, will receive a report (verbal, written, or both). More uncertain (and sometimes controversial) is whether the assessee will receive feedback. If so, will the feedback be verbal, written, or both, and under what circumstances? Ideally, if there is to be feedback, it should occur relatively soon after the assessment data have been gathered, and in some circumstances the feedback occurs immediately after the formal data collection process as a conclusion to the psychological interview.

As previously mentioned, the design of the assessment protocol is based on the underlying requirements or competencies for the position or job. The assessing psychologist will select the relevant tests (if any) to be administered, and often these will be both cognitive and personality measures. Additionally, interests are sometimes measured, and various types of simulations (e.g., role-play, in-basket) are often used. Most assessments include an interview with the assessing psychologist. The interview is often behaviorally focused and otherwise has several potential uses: (a) It can contribute to the interpretation of various test scores; (b) it can assess important requirements and competencies not measured by other assessment components; (c) it can provide background information so that the assessor is able to learn some things about the assessee beyond the set of test scores; and (d) it can be integrated with the feedback process and, when relevant, help resolve any conflicting information that may have come forth during the assessment process.

INTERPRETATION OF ASSESSMENT INFORMATION

Given the results of a psychological test battery and an interview, the psychologist now makes a series of judgments regarding the fit between the assessee and the position/job requirements and context. Some believe the fit is really of a multidimensional nature: person–position; person–team; person–organization; and, for international assignments, person–culture. In all circumstances, the interpretation and integration of the assessment information is not a matter of examining one or more cutoff scores to determine who passes, but rather it is the making of inferences about future behavior in the work setting. Moreover, the psychologist recognizes that the data collected about

the assessee are not perfect; the instruments do not have perfect psychometric properties; and the data (including the interview) are influenced by the self-presentation of the assessee.

Apart from concerns that may be raised about the quality and accuracy of the assessment data, the assessing psychologist is influenced by other matters. For example, what is the purpose of the assessment—to make a hiring decision? To consider an assessee for promotion? Or perhaps to give career direction? Also of importance is whether or not the psychologist has available useful or relevant normative data for each assessment component. Assuming the availability of normative data, when and how is it used? And how does the psychologist determine when to follow normative versus ipsative interpretations? There are no prescriptive answers to these questions, but every assessing psychologist has very likely encountered them.

Finally, the faking of assessment information is well documented, and many instruments (primarily personality tests) provide indexes of faking. Given that the faking indexes are high (or perhaps very low), how does the assessing psychologist incorporate this information into the interpretation of the data? Although there is no single answer to this question, it is a problem that must be addressed by assessors when interpreting test scores.

INTEGRATION OF ASSESSMENT INFORMATION

Although the research literature has generally found statistical combinations of assessment results to be more accurate than clinical judgment, the typical individual assessment relies on the psychologist's integration of the relevant information. This integration, of course, includes melding data obtained from tests, simulations, and the assessment interview. It also should include knowledge about the psychometrics of the assessment results and the influences of various demographic characteristics (including culture, gender, ethnicity, and age) on the various predictors. The ideal would be that all assessment instrumentation would be free of any biases, but we know that is not the case.

PSYCHOMETRICS

The psychometrics of individual psychological assessment is a particularly important yet confounded topic. The reliability and validity of the assessment process

have not been studied very often, and published research has focused on one of two facets of the psychometric domain. Because of its complex nature, the measurement of reliability and validity of individual assessments have multiple components. The instruments themselves (e.g., tests, interview) have psychometric qualities, as do the interpretation of the assessment data and the final description or recommendation offered by the psychologist. Also, the overall assessment context (e.g., hiring, career counseling) and appropriate criteria (e.g., job performance, development success) have potentially unknown confounding influences on attempts to study the validity of the individual assessment processes.

UTILITY

Given a lack of comprehensive validity evidence, it is reasonable to ask why individual assessment continues to survive and even flourish. Perhaps the answer lies with utility. Again, there is little research on this topic, but what seems to prevail among assessment providers and users is the notion that assessment, although perhaps not perfect, makes an important contribution to organizations' decision making. This may be even more accurate for selecting or promoting individuals to very critical or senior-level positions. Thus, anecdotal stories, proclamations, and similar types of information have prevailed, given the absence of research evidence to either support or refute the use of individual assessment.

ETHICAL ISSUES

Individual assessment can potentially create a variety of different types of ethical issues. These issues typically must be addressed by the assessing psychologist but also may be matters decided by the using organization. Confidentiality, informed consent, administration, and marketing are some of the major topics that can involve ethical concerns. Both the American Psychological Association and the Society for Industrial and Organizational Psychology publish materials relevant to the ethical practice of individual psychological assessment.

LEGAL ISSUES

At this time there are no legal decisions regarding individual assessment in organizational settings that

directly bear on the application of the typical type of assessment procedures that have been described in this discussion. This is apparently the case even though the assessment process, like other employment practices, is under the purview of the various statutes regarding equal employment opportunity at both the federal and state levels. Accordingly, assessing psychologists should make every attempt possible to ensure that the assessment process is in compliance with legal, ethical, and professional practice standards.

SUMMARY

Individual psychological assessment is one of the most prevalent components of the practice of industrial and organizational psychology. It is intended to support organizational decision making by making predictions regarding an individual's job success and performance, development, or organizational fit. Although there is a scarcity of research regarding the assessment process and associated outcomes, individual psychological assessment represents a blending of both art and science. It is especially challenging because it requires the assessing psychologist to interpret and integrate a variety of information about an individual and make predictions about his or her future behavior in a unique organizational setting.

INDIVIDUAL DIFFERENCES

Individuals differ from one another behaviorally in myriad ways. *Differential psychology*, the scientific study of these individual differences, provides an organizational structure for this vast array of psychological attributes. By examining broad behavioral patterns and using systematic assessments of relatively stable personal attributes, differential psychology allows longitudinal forecasting of a variety of important life outcomes. Because much of the research in this area focuses particular attention on predicting long-term life outcomes, and because work is such a large and important feature of adult life, the relationships between many commonly investigated individual difference constructs and various aspects of work behavior (e.g., educational-vocational choice, acquisition of job-related knowledge, job performance, job satisfaction and tenure) are well understood.

MEASUREMENT METHODS

Traditionally, the measurement of individual differences has relied on psychometric scales based on the aggregation of many items. Because any single item on a scale represents only a sliver of information about a personal attribute, aggregation is used to create a composite of several lightly correlated items. This approach distills the communality running through the items and constitutes highly reliable and useful information about the human characteristic under analysis.

Although individuals are commonly described in the more popular press in terms of *types*, implying that people are members of distinct categories (e.g., extraverts or introverts), individual difference variables are rarely observed as discrete classes. Rather, the majority of individuals are found near the center of a continuous distribution, with few observations at either extreme. The distributional pattern of most individual difference variables is well represented by the normal (bell-shaped) curve.

MAJOR DOMAINS

The major dimensions of individual differences can be classified into three overlapping clusters: cognitive abilities, preferences (interests and values), and personality. Each will be reviewed in turn, but cognitive

abilities will be focused on here because of their importance for industrial/organizational psychologists.

Cognitive Abilities

General Intelligence. The predominant scientific conceptualization of cognitive abilities involves a hierarchical organization. Various models of additional specific abilities have been proposed, but the hierarchical nature of human abilities is salient in each. For example, John Carroll factor analyzed more than 460 data sets collected throughout the 20th century and found a general factor (*g*) at the apex that explained approximately half of the common variance among a heterogeneous collection of tests, revealing a communality running through many different types of more specialized abilities and the tests designed to measure them.

This general intelligence factor exhibits an extensive range of external correlates, implicating it as arguably the most scientifically significant dimension of human psychological diversity uncovered by differential psychology to date. It has repeatedly demonstrated its utility in the prediction of educationally and vocationally relevant outcomes, including the acquisition of job-related knowledge and job performance. For example, in a meta-analysis of 85 years of research on personnel selection methods, Frank Schmidt and John Hunter reported that *g* is the best single predictor of performance in job-training programs, exhibiting an average validity coefficient of .56. Schmidt and Hunter further reported that the validity of *g* in predicting job performance is second only to that of work sample measures. However, because the use of work samples is limited to use with incumbents and is much costlier to implement, *g* is usually considered more efficient.

The predictive validity of *g* in forecasting job performance varies as a function of job complexity, with stronger relationships among more complex positions. Hunter reports validity coefficients of .58 for professional and managerial positions, .56 for highly technical jobs, .40 for semiskilled labor, and .23 for unskilled labor. For the majority of jobs (62%), those classified as medium-complexity, a validity coefficient of .51 was observed.

Specific Abilities. The general factor of intelligence is supplemented by several more circumscribed, specific abilities that have demonstrated psychological

importance. David Lubinski and his colleagues have shown that at least three add incremental validity to the variance explained by *g*: verbal, mathematical, and spatial abilities. The importance of specific abilities may be even more apparent at higher levels of functioning. In examinations of numerous job analysis data sets, for example, Linda Gottfredson found that, although the functional duties of jobs were characterized primarily by their cognitive complexity (i.e., demands on general intelligence), jobs requiring above-average intelligence were more dependent on profiles of specific abilities than were those jobs requiring average or below-average general intelligence.

Specific abilities are relevant in the prediction of job performance, but they are also important in predicting the educational and vocational niches into which individuals self-select. This self-selection occurs even at extraordinary levels of general intellectual development. In a recent 10-year longitudinal study, for example, Lubinski compared the educational-vocational tracks chosen by three groups of profoundly gifted individuals (top 1 in 10,000 for their age): a high verbal group (individuals with advanced verbal reasoning ability, relative to their mathematical ability), a high math group (individuals with advanced mathematical reasoning ability, relative to their verbal ability), and a high flat profile group (individuals with comparably high verbal and mathematical abilities). Despite having similar levels of general cognitive ability, the three groups diverged in their professional developmental choices. High math participants were frequently pursuing training in scientific and technological professions, whereas high verbal participants were doing so in the humanities and arts. High flat participants were intermediate. Spatial ability provides unique information beyond *g* also in understanding development in educational and vocational contexts. It has been shown to be a necessary component in several career clusters, including engineering, the physical sciences, and the creative arts.

Preferences

Modeling preference dimensions (interests and values) can be helpful also for understanding how people approach and operate within educational-vocational environments. John Holland has proposed a model that is particularly useful for interests. The origins of this model stemmed from atheoretical, empirical keying methodology in which the likes and dislikes of

incumbents across a variety of occupational categories were contrasted. Under the assumption that people in different occupations share common interests, which differentiate them from people in other occupations, measures of vocational interests compare an individual's combination of interests with the average interest profiles of individuals from various occupational groups as a means for vocational counseling and selection. This empirical approach led the way to a more cohesive theory of interest that contributes valuable information regarding how people operate in learning and work environments.

Holland's model of interests organizes six general occupational themes in a hexagon with one theme at each vertex in the hexagon. The themes are ordered according to their pattern of intercorrelations: Adjacent themes in the hexagon are more highly correlated to one another, whereas opposite themes are least correlated. This model is known as the RIASEC model, an acronym for the six themes represented in the hexagon: realistic, investigative, artistic, social, enterprising, and conventional. Individuals with high realistic interests exhibit preferences for working with things and tools; those with high investigative interests enjoy scientific pursuits; high artistic interests reflect desires for aesthetic pursuits and self-expression; social interests involve preferences for contact with people and opportunities to help people; individuals high in enterprising interests enjoy buying, marketing, and selling; and those with conventional interests are comfortable with office practices and well-structured tasks. Individuals' relative normative strengths on each of the RIASEC's general occupational themes are commonly assessed using the Strong Interest Inventory.

Although the generalizability of the RIASEC model has emerged repeatedly in large samples, Dale Prediger has suggested that the model can be reduced to two relatively independent bipolar dimensions: *people versus things*, and *data versus ideas*. *People versus things* may be superimposed on the social and realistic themes, respectively. Running perpendicular to the first dimension, the second dimension, *data versus ideas*, locates *data* between the enterprising and conventional themes and *ideas* between the artistic and investigative themes. The *people versus things* dimension represents one of the largest sex differences on a trait uncovered in psychology (a full standard deviation, with women scoring higher on the desire to work with people, and men, with things),

revealing important implications for the occupations that men and women choose.

Values constitute another category of personal preferences germane to learning and work, which have demonstrated their utility in the prediction of both educational and occupational criteria. Values are validly assessed by the Study of Values, which reports the intraindividual prominence of six personal values: theoretical, economic, political, social, aesthetic, and religious. These dimensions provided an additional 13% of explained variance above the 10% offered by math and verbal abilities in the prediction of undergraduate majors in gifted youth assessed over a 10-year interval; moreover, this finding has recently been generalized to occupational criteria, measured in commensurate terms, over a 20-year interval. However, although preferences do seem to play an important role in predicting occupational group membership and tenure, once individuals self-select into occupational fields, the utility of preferences for predicting job performance in those fields is limited.

Personality

Empirical examinations of personality use trait models to understand a person's typical interpersonal style and behavioral characteristics. These models have historically relied on a lexical approach that assumes that important dimensions of human personality are encoded in human language. This method has been fruitful: Lewis Goldberg, among others, has factor analyzed the lexicons of many languages and found a five-factor model of personality with remarkable similarities across cultures (see also investigations by Robert McCrae and Paul Costa). Although the labels for each of the factors have varied, similar underlying constructs consistently emerge: extraversion, agreeableness, conscientiousness, neuroticism, and openness to experience. Extraversion is characterized by terms such as *talkative*, *sociable*, or *not reserved*; agreeableness by *good-natured*, *cooperative*, or *not cold*; conscientiousness by *responsible*, *thorough*, or *not disorganized*; neuroticism (sometimes referred to as *emotional stability*, *reversed*) by *anxious*, *emotional*, or *not calm*; and openness to experience (sometimes referred to as *culture* or *intellect*) by *imaginative*, *reflective*, or *not narrow*. The normative standing of individuals on each of the dimensions of the five-factor model of personality is commonly assessed using the NEO Personality Inventory,

although an analogous instrument, the IPIP-NEO (IPIP is International Personality Item Pool), is available in the public domain at <http://ipip.ori.org/>.

Collectively (and sometimes individually), these broad dimensions of personality are valid predictors of occupational training and subsequent performance. For example, across multiple occupational categories, conscientiousness alone exhibits validity coefficients in the low .20s for predicting training and job proficiency. However, when conscientiousness was assessed in conjunction with emotional stability, Denise Ones and her colleagues have documented a coefficient of .41 for predicting job performance. This particular combination of personality factors, conscientiousness and emotional stability, is found in tests of integrity commonly used in personnel selection. (Robert Hogan and his colleagues reviewed these and other studies of personality in selection in 1996.)

Relationships Among Attributes

Although each of the major classes of individual differences—cognitive abilities, preferences, and personality—has traditionally been examined in isolation from the other two, these classes are not independent. Cognitive abilities, preferences, and personality traits tend to covary systematically to create constellations of personal attributes; and these complexes have interdependent developmental implications. Phillip Ackerman, for example, has proposed a theory of adult development that models the dependencies among individual difference attributes to describe how intellectual processes and knowledge are relevant to occupational performance across the life span. The cornerstones of Ackerman's theory are intelligence-as-process, personality, interests, and intelligence-as-knowledge. Intelligence-as-process regulates the complexity and density of the knowledge assimilated, whereas the development of intelligence-as-knowledge is guided by interest and personality attributes. Thus, intelligence-as-process, through interactions with interests and personality, fosters intelligence-as-knowledge.

How each individual attribute operates in a given person will vary according to his or her full constellation of attributes. Because all three classes of individual differences—cognitive abilities, preferences, and personality—influence the development of particular

knowledge structures over time, great variability exists among the knowledge bases of individuals who are similar on some dimensions but dissimilar on others. For example, two individuals with similar ability profiles, but with contrasting interests and personality traits, might exhibit markedly diverse behavioral patterns. Using a multidimensional approach to individual differences has important implications for understanding professional development: Richard Snow has outlined the importance of trait complexes in educational contexts, and Rene Dawis and Lloyd Lofquist have done so in a discussion of taxons in vocational settings.

Although vocational counseling and personnel selection frequently attend to individuals' strengths and salient interests and personality traits, another feature of personal profiles is relevant to these applications. Just as an individual's strengths and preferences influence the niches people self-select into and their subsequent likelihood of acceptable job performance and satisfaction with those occupations, their weaknesses and dislikes are relevant here, too. At the individual level, relative weaknesses and dislikes influence domains that people choose to avoid, but these attributes likely influence subsequent performance and satisfaction-related job tenure, as well.

CONCLUSION

Individual differences attributes and the constellations they form differentially attune people to contrasting educational-vocational opportunities (*affordances* for learning and work). From an individual's perspective, an appreciation of one's cognitive abilities, preferences, and personality provide invaluable insight for directing one's career development in personally rewarding ways. From an organizational perspective, one may use this information—available through measures of individual differences—to estimate the likelihood of desirable work behavior (e.g., citizenship, job performance, satisfaction, and tenure). Creating optimal niches for personal development and satisfaction (for the individual) and meeting the environment's goals and demands (for the organization) may be achieved simultaneously using an individual differences approach.

INDUSTRIAL RELATIONS

Industrial relations refers to relationships between employers and workers. In common parlance, the term is particularly associated with trade unions and the exercise of overt conflict, most notably by workers in the form of strikes, picketing, and work-to-rules, although employers’ lockouts of workers and explicit resistance to trade unions’ attempts to recruit workers are also significant. *Trade unions* are associations of workers that provide a distinctive form of empowerment, as they are independent of management and have an existence beyond the boundaries of the organization. In most countries, trade union rights are protected by the state, although this protection may take a variety of forms. Trade union rights may be part of a country’s constitution, as is the case, for example, in Germany, Italy, Sweden, Brazil, and South Africa. In contrast, in North America and the United Kingdom, where no such constitutional rights exist, there are laws defining the processes of the certification of trade unions so their independence from management is protected.

INDUSTRIAL RELATIONS AS A FIELD

Industrial relations has also been defined, especially in North America, the United Kingdom, and Australasia, as a field of study within the social sciences. Spawned by the rise of trade unions and the conflict associated with the management–worker relationship, it was particularly strong in the immediate postwar period. As the study developed, attempts to define its scope stressed that it extended beyond trade unionism so it included forms of regulation other than collective bargaining and, particularly, the law and unilateral rule making by management or work groups. It was also concerned with substantive labor problems such as low pay, job insecurity, health and safety risks, poor working conditions, and unequal opportunities, and not just procedural problems involved in the handling of conflict, as well as the more general issues of economic efficiency and social justice.

Nonetheless, much academic study was centered on trade unions, as they were seen as a vital concomitant of industrialization and political liberalization in most countries. As trade unions’ influence grew to unprecedented heights in developed countries in the

1950s, social theorists saw them as a key ingredient of the capitalist economy and symbols of the maturity of liberal democratic societies, which within the Cold War era were contrasted with communism. Trade unions were seen to offer workers a channel to air their grievances and ensure due process in the workplace. Their core activity, collective bargaining with management, provided a means by which the benefits of productivity growth could be distributed in a fair way, and in the wider political arena, trade unions could serve as vital intermediary organizations in pluralist societies.

THE ROLE OF TRADE UNIONS

Yet through the 1960s and 1970s, particularly in the United States and United Kingdom, the activities of trade unions increasingly became a source of concern among employers, governments, and the public. The purported role of unions in fueling inflation, and their potential negative effect on cost reduction, technological innovation, and productivity growth, were given particular prominence. Research has confirmed that wages tend to be higher in unionized firms, although the effect of unions on productivity and technical change is less clear-cut.

A core foundation of the industrial relations field is that unions have two sides, a monopoly and a voice face, and that because of this duality they can potentially affect organizational performance positively or negatively. The monopoly face is likely to reduce organizational performance as their power to bargain for better wages and fringe benefits means that unions secure for their members a greater proportion of the company's surplus revenue and hence reduce profits. Moreover, unions can negotiate rules regulating jobs (often known as *restrictive practices*) that may constrain the optimal allocation of labor. These rules cover issues such as internal job mobility, redundancy, the allocation of overtime, demarcations between occupations, and working conditions.

In contrast, through their voice face, unions may have positive effects on performance. By providing a conduit for employees to have their say, unions help to retain skilled labor and to motivate employees, because workers can use the union to redress grievances and dissatisfactions rather than leave the organization. Moreover, employee voice may be used to suggest improvements in working practices, training methods, and safety procedures. This cooperative

dimension of employment relations is part of what is increasingly being labeled a *partnership approach*, in contrast to the adversarial one traditionally assumed to dominate union behavior. An additional way in which trade unions may contribute positively to organizational performance is in their role as agents of effective management. More specifically, union representatives, as a result of their involvement in collective bargaining, both legitimize and help to police agreements.

PUBLIC POLICY AND THE TRANSFORMATION OF INDUSTRIAL RELATIONS

The public policy concerns generated by the problems of industrial relations in the 1970s and 1980s particularly focused on the monopoly side of trade unions and served to heighten interest in the field. Much study had a pragmatic orientation, as many scholars, viewing collective bargaining as the best way to conduct industrial relations, were concerned with improving such bargaining. They focused on reforming the institutions of industrial relations—for example, by consolidating the growing importance of bargaining at the organizational rather than the industrial level.

Nonetheless, fueled greatly by neoclassical economics and neoliberal political theory, the roles of collective bargaining and trade unions were increasingly questioned as their negative effects on economic performance at both the firm and national level were emphasized. Governments, and particularly neoliberal governments such as Ronald Reagan's administration in the United States (1980–1988) and the Conservative governments in the United Kingdom (1989–1997), acted on these criticisms by introducing new state controls on the trade unions. The 1980s marked a transformation of industrial relations in these and other countries, and much study of industrial relations in the late 20th century focused on the nature and causes of this development.

A major element of the changing landscape of industrial relations has been the almost universal decline in trade union membership and influence, accompanied by a decline in strikes, particularly in the private sector. This is true even in countries such as Germany and the Netherlands where there is a dual industrial relations system, in which collective bargaining is predominantly at the industry level and is supplemented by legally based works councils at the organizational level. The exceptions to such broad

trends in declining union influence are mainly in countries freed from military dictatorships or other forms of political repression in the past 20 years, such as Brazil and South Africa.

Coinciding with this union decline, increasing attention has been given to new forms of human resource management (HRM) practices associated with the so-called high performance organization model (often referred to as *high-involvement management*), many of which were pioneered in large non-unionized U.S. firms such as IBM. These are taken to reverse many of the practices associated with scientific management and Taylorist forms of organization, the negative effects of which had helped to fuel a desire for unionism. The new HRM has even been seen by some as a means by which management is aiming to substitute the union for unilateral management control—for example, through directly communicating with workers, linking pay more directly to performance, and enhancing the role of team leaders at the expense of union representatives. Mirroring these changes in unions, some have questioned industrial relations as a field of study, both from outside and within, suggesting, for example, that it will be subsumed within the study of HRM.

THE BROADENING OF THE FIELD OF INDUSTRIAL RELATIONS

There is little evidence to suggest that HRM is substituting for trade union representation, and certainly elements of both coexist in many organizations in a variety of countries. The field of industrial relations has, nonetheless, broadened to encompass the study of the development of high-performance practices and other elements of HRM. It is thus now accommodating wider developments in management to a greater extent than it has in the past. Moreover, the law and other institutions of the state have played an increasingly important role in most societies, both in regulating the institutions of industrial relations and in directly addressing labor problems such as low pay, health and safety risks, and unequal opportunities. Through studying these and other developments, the field has moved well beyond its past overemphasis on trade unions. Increasing salience has also been given to alternative forms of representation to trade unionism, notably works councils, which, as legally constituted in some European countries, are independent from management. This has also fueled a renewed

interest in comparing industrial relations practice across countries, particularly in light of the emphasis in political theory on varieties of capitalism (e.g., coordinated and liberal market economies). As employee voice is no longer equated with trade unions, it is increasingly acknowledged that the use of multiple channels for employee (and employer) voice is likely to be the norm. Thus the field of industrial relations is giving way to a broader notion of employment relations centered on different voice regimes. Symbolic of this, the United States' main professional body, the Industrial Relations Research Association, changed its name in 2005 to Labor and Employment Relations Association.

INDUSTRIAL/ORGANIZATIONAL PSYCHOLOGY AND INDUSTRIAL RELATIONS

Industrial/organizational psychology has contributed to the study of industrial relations in a variety of ways, although its influence compared with disciplines such as economics, sociology, and political science has been relatively small. First, psychology has contributed through studying conflict and modes of resolution, particularly through its emphasis on perceptions and attitudes. For example, the study of the way in which group consciousness forms, which involves social comparison processes, is important for defining what an individual considers to be fair treatment and appropriate rewards. Second, psychology has contributed through studying why people join and participate in trade unionism, and more broadly why they value certain types of participation and voice in the workplace. Third, psychologists have studied many of the substantive issues that lie behind the grievances that constitute labor problems, including job insecurity, job design, discrimination, and most recently workplace violence and bullying. In addition, the methods used in empirical studies by industrial relations scholars have been influenced by psychology, most notably their use of factor analysis and structural equation modeling. The attempts by psychologists to make qualitative research more systematic may yet be significant in the study of employment relations.

INFERENCE STATISTICS

A frequent goal of collecting data is to allow inferences to be drawn about a population from a sample. In such cases, inferential statistics provide the bases on which to draw such conclusions that go beyond the observed data. An example of a common inference is evaluating the likelihood that an observed effect (e.g., difference in group means) is not attributable to chance. Unlike descriptive statistics that simply summarize observed data, inferential statistics are used to make more general statements about the world beyond the data. Most of the frequently reported inferential statistics are derived from the general linear model. Some examples are *t* tests, analysis of variance (ANOVA), linear regression analysis, and factor analysis.

Inferential statistics are based on the notion of sampling and probability. The problem to be overcome in conducting research is that data are typically collected from a sample taken from a larger population of interest. If the data collected from the sample are not representative of the data associated with the population, inferences drawn from the sample data are not warranted. For example, consider the case in which a researcher is interested in how employees feel about a new organizational policy and chooses to sample 20 individuals from the larger organization consisting of

1,000 employees. The inferences drawn from this sample are likely to be less justified than if the sample had been larger (e.g., 100). In addition to sample size, characteristics of the sample are also important. Using the previous example, 20 randomly selected individuals may be more representative than 100 individuals who share some unique characteristics (e.g., all work the night shift) and thus may provide a stronger basis for drawing inferences about employee attitudes.

Probability is another important concept related to inferential statistics. Probability theory provides the basis for accepting or rejecting hypotheses. Traditional hypothesis testing casts inferential statistics as providing the basis of a dichotomous decision. In short, if the null hypothesis were true (i.e., no effect), what is the probability of observing the effect? To the extent that the answer to this question is a low value (typically less than 5%), the null hypothesis is rejected and the inference is made that the observed effect was not likely the result of chance. Instead, the effect is considered real.

As an alternative to null hypothesis significance testing, confidence intervals may be used as the basis for drawing inferences. The fundamental idea underlying confidence intervals is that a given effect may be overestimated or underestimated in a specific study. Confidence intervals are derived from the point estimate of the observed effect, and the width of the interval is determined by the standard error of the estimate of the effect. A benefit to using confidence intervals is that they provide more information (i.e., a range of reasonable values for the estimated parameter) than traditional dichotomous hypothesis tests.

Generally, inferential statistics require four pieces of information. First, a measure of the size of the observed effect is required. This effect size estimate can take the form of an observed difference between groups (e.g., *d*) or can be expressed in terms of the magnitude of relationship between variables (e.g., *r*). These effects are referred to as *estimates of the population parameter of interest*. Such estimates provide for stronger inferences, to the extent that they are unbiased. All else being equal, the larger an observed effect, the more likely it is that an inference will be drawn that the effect is real. Second, sample size influences the inferences drawn from data. In general, larger samples permit drawing stronger inferences than smaller samples. Third, the Type I error rate (i.e., *p*) associated with the statistical test of the observed effect influences the inferences drawn from observed

results. Finally, the power of the statistical test influences the extent to which inferences are justified. Greater power leads to stronger inferences.

METHODS FOR PERSONNEL SELECTION

INNOVATION

Innovation is defined as the successful implementation of a creative idea. Some suggest that although creativity needs to be truly novel, innovation can be the adaptation of ideas in the current environment (so the idea is novel in this organization, but not completely novel). Others see *innovation* as a more inclusive term including both idea generation and its implementation. *Innovation* has also been defined as only the implementation aspect, excluding the idea generation and development phase. Common to all these definitions is the focus on the implementation of an idea, process, or product. Therefore, much of the work on innovation focused on the antecedents and consequences for successful implementation.

ANTECEDENTS

Much of the work done to understand the factors that influence organizations in adopting innovation has focused on organizational determinants. Organizational climate in particular has received attention as a contributing factor. Support for innovation, support for risk, and trust have emerged as important climate factors. Studies investigating the role of leadership in

innovation have found that transformational leaders create a climate that provides support for innovation, as well as providing the intellectual stimulation that is necessary for innovation. In addition, an important role for the leader in supporting innovation is removing obstacles—such as providing information, resources, administrative support, and clarity, as well as serving as a champion for innovation. Flexible organizational structures and jobs have been linked to innovation. Specifically, jobs that allow for more discretion and autonomy and organizational structures that are less centralized and adapt quickly have been linked to the promotion and adoption of innovation.

Team factors that emerged as contributing to innovation are group composition and group processes. To facilitate innovation, the group must possess the required skills and knowledge. Groups heterogeneous in skills and knowledge may be more likely to innovate successfully. However, diversity of background may also lead to group conflict, which would result in less innovation. It has been suggested that there is an optimal level of diversity that will facilitate innovation based on the task and group processes. Group processes that focus on participation, commitment, and managing conflict effectively are suggested to enhance innovation. With regard to conflict, it has been suggested that some degree of task conflict (focusing on the task) may facilitate innovation but personal or relational conflict (focusing on interpersonal relationships) can hinder innovation. In addition, research on minority dissent and innovation shows that minority dissent can lead to more innovation in teams if team climate is constructive and supportive of risk and participation.

Individual factors are the focus of idea generation and creativity research; however, some innovation research has looked at individual factors. Because innovation requires the successful implementation of a novel idea, one important individual characteristic contributing to innovation is perseverance. Original ideas tend to be rejected because they are new, untried, and therefore risky. For innovation implementation to occur, someone, either the idea generator or a champion, must persistently present the idea and its merits for it to be adopted.

Finally, the external environment is also seen as an important antecedent to innovation. It has been suggested that innovation occurs as a result of threat or demands from the external environment. Moreover, it has been suggested that external demands will have a

negative impact on idea generation but a positive impact on innovation.

OUTCOMES

Innovation is typically considered the criterion in most studies. Although empirical research has looked at the effect of individual creativity and its effect on team creativity and innovation, only limited empirical work is available on the consequences of innovation. Much of that research has focused on the organizational and financial consequences of innovation, such as new products, increase in market share, and organizational adaptation and survival.

INPUT–PROCESS–OUTPUT MODEL OF TEAM EFFECTIVENESS

Much of the work in organizations is accomplished through teams. It is therefore crucial to determine the factors that lead to effective as well as ineffective team processes and to better specify how, why, and when they contribute. Substantial research has been conducted on the variables that influence team effectiveness, yielding several models of team functioning. Although these models differ in a number of aspects, they share the commonality of being grounded in an input–process–output (IPO) framework. *Inputs* are the conditions that exist prior to group activity, whereas

processes are the interactions among group members. *Outputs* are the results of group activity that are valued by the team or the organization.

The IPO model has historically been the dominant approach to understanding and explaining team performance and continues to exert a strong influence on group research today. The framework is based on classic systems theory, which states that the general structure of a system is as important in determining how effectively it will function as its individual components. Similarly, the IPO model has a causal structure, in that outputs are a function of various group processes, which are in turn influenced by numerous input variables. In its simplest form, the model is depicted as the following:

Input → Process → Output

INPUTS

Inputs reflect the resources that groups have at their disposal and are generally divided into three categories: individual-level factors, group-level factors, and environmental factors. *Individual-level factors* are what group members bring to the group, such as motivation, personality, abilities, experiences, and demographic attributes. Examples of group-level factors are work structure, team norms, and group size. Environmental factors capture the broader context in which groups operate, such as reward structure, stress level, task characteristics, and organizational culture.

PROCESSES

Processes are the mediating mechanisms that convert inputs to outputs. A key aspect of the definition is that processes represent interactions that take place among team members. Many different taxonomies of teamwork behaviors have been proposed, but common examples include coordination, communication, conflict management, and motivation.

In comparison with inputs and outputs, group processes are often more difficult to measure, because a thorough understanding of what groups are doing and how they complete their work may require observing members while they actually perform a task. This may lead to a more accurate reflection of the true group processes, as opposed to relying on members to self-report their processes retrospectively. In addition, group processes evolve over time, which means

that they cannot be adequately represented through a single observation. These difficult methodological issues have caused many studies to ignore processes and focus only on inputs and outputs. Empirical group research has therefore been criticized as treating processes as a “black box” (loosely specified and unmeasured), despite how prominently featured they are in the IPO model. Recently, however, a number of researchers have given renewed emphasis to the importance of capturing team member interactions, emphasizing the need to measure processes longitudinally and with more sophisticated measures.

OUTPUTS

Indicators of team effectiveness have generally been clustered into two general categories: group performance and member reactions. *Group performance* refers to the degree to which the group achieves the standard set by the users of its output. Examples include quality, quantity, timeliness, efficiency, and costs. In contrast, *member reactions* involve perceptions of satisfaction with group functioning, team viability, and personal development. For example, although the group may have been able to produce a high-quality product, mutual antagonism may be so high that members would prefer not to work with one another on future projects. In addition, some groups contribute to member well-being and growth, whereas others block individual development and hinder personal needs from being met.

Both categories of outcomes are clearly important, but performance outcomes are especially valued in the teams literature. This is because they can be measured more objectively (because they do not rely on team member self-reports) and make a strong case that inputs and processes affect the bottom line of group effectiveness.

STEINER'S FORMULA

Consistent with the IPO framework, Ivan Steiner derived the following formula to explain why teams starting off with a great deal of promise often end up being less than successful:

$$\text{Actual productivity} = \text{potential productivity} - \text{process loss}$$

Although potential productivity is the highest level of performance attainable, a group's actual productivity often falls short of its potential because of the existence of process loss. *Process loss* refers to the suboptimal ways that groups operate, resulting in time and energy spent away from task performance. Examples of process losses include group conflict, communication breakdown, coordination difficulty, and social loafing (group members shirking responsibility and failing to exert adequate individual effort). Consistent with the assumptions of the IPO model, Steiner's formula highlights the importance of group processes and reflects the notion that it is the processes and not the inputs (analogous to group potential) that create the group's outputs. In other words, teams are a function of the interaction of team members and not simply the sum of individuals who perform tasks independently.

LIMITATIONS OF THE IPO MODEL

The major criticism that has been levied against the IPO model is the assumption that group functioning is static and follows a linear progression from inputs through outputs. To incorporate the reality of dynamic change, feedback loops were added to the original IPO model, emanating primarily from outputs and feeding back to inputs or processes. However, the single-cycle, linear IPO path has been emphasized in most of the empirical research. Nevertheless, in both theory and measurement, current team researchers are increasingly invoking the notion of cyclical causal feedback, as well as nonlinear or conditional relationships.

Although the IPO framework is the dominant way of thinking about group performance in the teams literature, relatively few empirical studies have been devoted to the validity of the model itself. In addition, research directly testing the input–process–output links has frequently been conducted in laboratory settings, an approach that restricts the number of relevant variables that would realistically occur in an organization. However, although the IPO model assumes that process fully mediates the association between inputs and outputs, some research has suggested that a purely mediated model may be too limited. Therefore, alternative models have suggested that inputs may directly affect both processes and outputs.

SUMMARY

Without question, the IPO model reflects the dominant way of thinking about group performance in the groups literature. As such, it has played an important role in guiding research design and encouraging researchers to sample from the input, process, and output categories in variable selection. Recent research is increasingly moving beyond a strictly linear progression and incorporating the reality of dynamic change. In addition, alternatives to the traditional IPO model have been suggested in which processes are not purely mediated.

INTEGRITY AT WORK

You need look no further than the newspaper headlines to see that issues of integrity have become paramount in the workplace. Scandal, abuse of power, theft, and assorted other problems have contributed to poor public images for many organizations and led to the downfall of others. The problem with integrity is twofold. First, how do we understand what integrity is, and second, how can we identify integrity in a functional sense?

INTEGRITY CONCEPTUALIZED

Integrity may be defined as demonstrating honesty and reliability at work, and generally behaving in accord with established standards and practices of an organization. In fact, for many years the words *integrity* and *honesty* were used interchangeably. It is

only lately that the definition of *integrity* has been expanded to include other forms of counterproductive (or *deviant*) behaviors, the common elements of which are that the behaviors (a) do not contribute, either directly or indirectly, to the functioning of the organization and (b) constitute a violation of either implicit or explicit norms or policies of the organization or surrounding community.

This leaves a great deal of leeway in understanding what *integrity* means in practice. It may be as simple as employee theft, or as complicated as the accounting frauds that plagued a number of high-profile organizations in recent years. The blanket definition of *integrity* also subsumes behaviors such as the use of illegal drugs, alcohol, and sometimes tobacco products, misappropriation of petty cash, and unwarranted absenteeism. Because all of these behaviors cost organizations money, it is of both theoretical and practical value to move beyond conceptualizing integrity purely in terms of honesty and to consider it in a broader context.

Costs of Low Integrity

Whether the definition chosen for *integrity* is broad or narrow, however, it is clear that organizations are rightly becoming more concerned with identifying individuals low in integrity. Estimates of employee theft in the United States alone were in excess of \$400 billion annually in recent years, although it is worth noting that even the definition of *theft* is inconsistent. Some organizations (and indeed, some approaches to assessing integrity) treat an employee who takes a long lunch as stealing time, treating wages lost while the individual was not at his or her desk as accountable theft, whereas others do not.

Higher-profile examples of low integrity also abound. Enron, WorldCom, and a variety of other organizations have recently come under fire for what might kindly be called low-integrity accounting practices. Although estimates vary on the actual costs the failure of such companies may have had for shareholders (depending on the source, Enron shareholders lost between \$1.2 million and \$70 billion, while WorldCom shareholders may have lost as much as \$100 billion), there can be no doubt that there have been nonmonetary consequences to a great many organizations as a result. Such demonstrations of low integrity can severely damage corporate reputations, leading to loss of business, profits, and jobs. They

also engender problems with loyalty, organizational commitment, motivation and retention, and, perhaps most damaging, trust. This lack of trust—on the part of both employees and the general public—in whether organizations have the best interests of both the community and the organization’s many stakeholders at heart can easily be the difference between success and failure.

Perhaps the major difficulty with integrity is identifying individuals who lack integrity *before they have the opportunity to harm the organization*. Although the assessment of integrity is treated in more detail elsewhere in this volume, it is important for us to understand three key pieces of what scientists refer to as the *operationalization* of integrity. That is, if we wish to identify individuals who are high and low in integrity, what do we look at?

INTEGRITY OPERATIONALIZED

It should be clear from the previous discussion that a great deal is subsumed under the heading *integrity*, and there are many potential signs that integrity either is or will become an issue for any member of the organization. When asked to describe how they might identify people low in integrity, there is a temptation on the part of many to simply say, “I know it when I see it.” The issue is much more complicated than that, however, and the fact of the matter is that few people are exceptionally good at recognizing individuals who are likely to demonstrate low integrity based on a casual (or even not-so-casual) interaction. Integrity has behavioral, attitudinal, and trait components, each of which will be discussed in turn.

Behavioral Integrity

Behavioral integrity is what concerns many organizations. Indeed, most of the examples noted above are behavioral in their focus. Theft is a behavior in which a member of the organization takes the organization’s resources—money, toner cartridges, or paper clips—for personal use and/or without the sanction of the organization. Embezzlement, fraud, the use of drugs on the job, and countless other behavioral examples abound of low integrity.

The difficulty with using an individual’s behaviors as a means of judging integrity is that although low-integrity behaviors may be common in organizations

(remember that \$400 billion in annual theft?), actually catching people in the act, or having them admit to such behaviors, is not. By the time lack of behavioral integrity is evident, the damage has been done. The ability to say that mistakes were made, that someone of questionable integrity was put into a position from which he or she could harm the organization, is less valuable than the capacity to identify such individuals in advance. Therefore, although many organizations focus on behavioral aspects of integrity, these may prove less valuable than the other methods of functionally defining integrity.

Attitudinal Integrity

One of the precursors of low-integrity behavior is necessarily an attitude that such behaviors are, if not acceptable, then at least normal. Individuals with the potential to cause integrity-related problems for organizations may say things like, “You can’t weed out all the problem employees, since everyone gives in to temptation from time to time.” Such statements, although potentially true, may reveal a great deal about the speaker, even if they must be interpreted with caution. A statement such as “There’s no way to stop people from stealing office supplies” may reflect an acceptance of a theft norm, or it may simply reflect a level of learned helplessness on the part of a person who has tried (and failed) to stop such behaviors.

The notion of *norms* becomes very important in understanding attitudinal integrity. When an employee begins to accept theft, fraud, or whatever other counterproductive behavior is common in the organization as a recognized part of daily operations, the psychological prohibitions against engaging in such behaviors break down. Pundits have noted that it is unlikely, for example, that the employees of Enron could have remained completely unaware that their organization was engaging in unethical business practices. Indeed, the individual credited with being a whistle-blower in the Enron case did not go public with the damaging information, choosing instead to keep it internal in an attempt to prevent the organization from suffering in the public eye. The norms of the organization were strong enough that even though she uncovered significant accounting problems, she reportedly did not go to the board of directors, did not go to the media, and did not resign. When an organization’s norms (and, in this case, the financial futures of many of its employees) allow for or encourage unethical or immoral

behaviors, it should come as a minimal surprise when the attitudes of its employees shift toward an acceptance of lower integrity.

Employers, then, need to be aware of potential indicators of attitudinal indicators of potential integrity problems. Questions such as “Would you say everyone is a little dishonest?” (a variation on which appears in a number of published measures of integrity) are relatively unambiguous. More ambiguous statements (e.g., “Close enough for government work!”), which *may* indicate low integrity, should be viewed with caution and in some respects resemble a projective personality test. If we are truly concerned with personality as a means of understanding integrity, research indicates that we would be much better served by using a trait-based approach.

Trait Integrity

A third approach to functionally identifying individuals likely to engage in low-integrity behavior is to begin with the notion that integrity is actually a trait, or a constellation of traits, that is part of an individual’s personality. One of the most widely researched facets of personality is the conscientiousness factor, common to the five-factor model of personality, as well as other approaches. Conscientiousness subsumes a number of other traits, including orderliness, diligence, and general honesty; the conscientious person tends to show up for work on time, do her work in as professional a manner as possible, and generally demonstrate the behaviors taken to be indicative of high integrity. It should come as no surprise that this personality trait has sometimes made its way into our understanding of integrity. Other personality facets that have sometimes been considered as aspects of integrity include emotional stability as well as factors such as locus of control and achievement orientation that were likely socialized into individuals at a young age.

SUMMARY

What constitutes integrity at work? Clearly, this is a complex issue. With behavioral, attitudinal, and trait components, and based as it is on both organizational and cultural norms, the meaning of *integrity* can be difficult to pin down. What cannot be disputed is its importance; the costs of low-integrity behaviors are well documented in the research and popular

literatures, and it can only be to the benefit of organizations to encourage integrity in their employees.

INTEGRITY TESTING

Paper-and-pencil tests designed to measure integrity, honesty, dependability, and related constructs have been in existence since at least the 1950s and have long been used in the retail sales, banking, and food service industries. Following the 1988 Employee Polygraph Protection Act, a federal law that restricted the use of the polygraph (i.e., the so-called lie detector), integrity testing grew substantially and spread into a wider range of industries and applications.

Although the individual tests differ in a number of specifics, there are a number of features common to virtually all integrity tests. In particular, integrity tests usually include items that refer to one or more of the following areas: (a) direct admissions of illegal or questionable activities, (b) opinions regarding illegal or questionable behavior, (c) general personality traits

and thought patterns thought to be related to dishonesty (e.g., the tendency to constantly think about illegal activities), and (d) reactions to hypothetical situations that may or may not feature dishonest behavior.

OVERT VERSUS PERSONALITY-BASED TESTS

A distinction is usually drawn between tests that inquire directly about integrity, asking for admissions of past theft, or asking about the degree to which the examinee approves of dishonest behaviors (often labeled *overt* tests), and tests that indirectly infer integrity on the basis of responses to questions that are not obviously integrity-related (often labeled *personality-based* tests). However, the distinction between overt and personality-based tests is not always a simple one. Many overt tests include items, scales, and so forth that are not obviously related to honesty, and many personality-based tests contain items that might alert the respondent to the true purpose of the test.

Overt tests usually include direct or indirect measures of perceptions of norms relating to honesty. The rationale for this type of measure is that individuals who believe dishonesty, theft, and so on are common and widely accepted are more likely to engage in these behaviors themselves. Even questions that ask for admissions of wrongdoing are probably best understood as measures of perceived norms. Individuals who admit to theft, dishonesty, and rule breaking when responding to an integrity test often believe that the behaviors they are admitting to are in fact widespread and at least implicitly accepted.

Personality-based tests often measure constructs such as thrill seeking, socialization, and resistance to authority. More recent tests have incorporated broad dimensions of personality that have been empirically linked to theft and counterproductive behavior, notably conscientiousness, agreeableness, and emotional stability.

Integrity tests (both overt and personality-based) appear to measure a range of constructs, and there is disagreement over the assumption that a general honesty or integrity factor underlies these tests. Various tests use unique scoring systems, and it is unwise to assume that tests are interchangeable.

VALIDITY OF INTEGRITY TESTS

Early reviews of integrity test validity came to discouraging conclusions, but since the late 1980s, both

narrative reviews and meta-analyses of integrity test validity have suggested that integrity tests are useful for a variety of purposes.

In discussing validity evidence, it is important to identify the specific criteria used in different studies. Some studies have validated integrity tests against measures of counterproductive behavior, whereas others have validated these tests against measures of general job performance. For example, scores on integrity tests show average correlations of .21 and .33 with measures of job performance and counterproductivity, respectively (correcting for unreliability and a variety of statistical artifacts, the estimated population correlations are .34 and .47, respectively). These two criteria are clearly not independent; employees who engage in a wide variety of counterproductive behavior are unlikely to be good performers. Nevertheless, there are important differences between the two criteria and, more important, differences in the criterion-related validity of integrity tests for predicting the two.

Construct Validity

There are several challenges in evaluating the construct validity of integrity tests. It is exceedingly difficult to define honesty, integrity, or whatever attributes these tests are designed to measure. Different tests seem to focus on very different attitudes, beliefs, or behaviors. For example, there are a number of definitions of *employee theft*. Researchers often distinguish between trivial and nontrivial theft; conclusions about the extent of theft depended largely on whether taking articles of little value (e.g., pencils, paper, supplies) was included in one's definition of *theft*. Goldbricking, taking long lunch breaks, using company time to carry out personal business, and similar activities are sometimes labeled *time theft*.

A related issue has been a source of controversy for nearly a century—the question of whether honesty is a distinct trait. Most researchers believe that situational factors have a strong impact on the tendency to engage in honest versus dishonest behaviors and that labeling a person as honest or dishonest is a serious oversimplification.

Informed consent is a potentially serious issue in integrity testing. Integrity test publishers often advise against informing examinees of their test scores. This implies that if an individual is denied employment on the basis of a score on an integrity test, he or she should not be so informed. The Standards for

Educational and Psychological Testing and the Ethical Principles of Psychologists make it clear that psychologists involved in integrity testing are obliged to inform examinees of the risks and consequences of taking the test versus refusing to take the test, the purpose and nature of the test, and the way in which test scores will be used.

Finally, there are serious concerns over the way in which integrity tests are scored and in which scores are reported. It is common to use some sort of dichotomous scoring (e.g., pass–fail) in integrity testing. More sophisticated tests sometimes report test scores in terms of a small number of zones: high danger, moderate danger, average danger, or low danger of theft, substance abuse, and so on. Test scores that are reported on a pass–fail basis are inherently suspect because they blur potentially meaningful differences between individuals in each of the two categories (e.g., it is unlikely that all individuals who fail present the same risks).

OVERALL ASSESSMENT OF INTEGRITY TESTS

Integrity testing was the focus of a great deal of controversy and debate in the late 1980s, when these tests first emerged into the mainstream. The American Psychological Association appointed a task force to examine integrity testing; their general conclusions provide a useful framework for evaluating integrity tests. In their 1991 report, they noted that integrity tests shared many of the strengths and weaknesses of other psychological tests and that well-developed tests showed acceptable evidence of reliability and validity to justify their use. There are still valid concerns about the use of bad tests and unwise testing practices when assessing integrity, but these concerns are not categorically different from concerns that can be raised in contexts where most psychological tests are used. Integrity tests are not broadly accepted as potentially useful assessment tools.

Integrity testing was once regarded as a field at the fringe of respectability. Integrity test publishers were regarded as secretive and (ironically) unreliable. In the last 20 years, there has been considerable progress in integrity testing and a very healthy interchange between test publishers and researchers interested in understanding the causes and consequences of integrity in the workplace. It now seems clear that the controversies over integrity testing in the 1980s and 1990s have proved beneficial to both test developers,

who have improved both their products and the process by which tests are developed and researched, and the users of integrity tests, who have increasing access to empirically validated measures that provide information about the dependability of job applicants.

INTERGROUP RELATIONS

Intergroup relations involve the feelings, evaluations, beliefs, and behaviors that groups and their members have toward another group and its members. Negative intergroup relations typically involve prejudice (negative feelings and evaluations), stereotypes (beliefs about groups and their members), and discrimination (unfair treatment). However, intergroup bias does not necessarily require negative orientations. Bias may reflect unusually favorable attitudes and beliefs about members of one's own group and preferential treatment toward them. The nature of intergroup relations is determined by psychological processes associated with social categorization, by the personalities and

motivations of group members, and by the functional relationship between the groups. These processes apply to a wide range of groups, including work teams, divisions within an organization, companies, and countries.

SOCIAL CATEGORIZATION AND INTERGROUP RELATIONS

Social categorization involves identifying people primarily on the basis of overt similarities and presumed group membership. Because group membership is critical to human functioning and survival, the tendency to categorize people as members of different groups is fundamental to social perception. This social categorization process, however, involves more than distinguishing people by group membership. The recognition of different group memberships initiates a number of biases that influence intergroup relations in systematic ways. Social identity theory and, more recently, self-categorization theory address the fundamental processes associated with social categorization.

When people are categorized into groups, even if the groups have no obvious functional relationship or enduring meaning, actual differences between members of the same category tend to be perceptually minimized, whereas differences between groups tend to be exaggerated. Moreover, people critically distinguish between individuals who are members of their group (the in-group) and those who are members of other groups (the out-groups). In general, when the intergroup boundary between the in-group and out-group is salient, people remember positive information better about in-group than about out-group members, discount negative actions by in-group members more than for out-group members, and ascribe positive attributes more strongly to the character of in-group than of out-group members. In addition, people behave in more favorable, intimate, and helpful ways toward in-group members. Feeling more positively about one's own group relative to others can enhance one's self-esteem. Thus, the mere awareness of the existence of different group memberships, when the groups are not interdependent and group membership is arbitrarily determined, typically produces bias.

These intergroup biases are particularly evident when people's social identity (their identity based on group membership) is more salient than their personal identity (their identity as a unique individual). For example, people are less trusting and behave in a

greedier fashion when collective identities are salient than when personal identities are salient.

INDIVIDUAL DIFFERENCES AND INTERGROUP RELATIONS

In addition to differences in the strength of group identity, individual differences in personality and values can influence the nature of intergroup relations. The personality variable of authoritarianism has historically received substantial attention with respect to intergroup attitudes and relations. Research in the 1950s concluded that the authoritarian personality, which is rooted in unhealthy family dynamics, is associated with unusual respect for authority and hierarchy, as well as strong distinctions between the in-group and out-group. Recent research has found that people high on right-wing authoritarianism have negative attitudes toward members of a number of other groups, particularly when the groups are perceived to violate society's morals and standards.

Social dominance theory, an alternative perspective, assumes that people who are strongly identified with high-status groups and who see intergroup relations in terms of group competition will be especially prejudiced and discriminatory toward out-groups. People high in social dominance orientation, an individual difference measure, believe that group hierarchies are inevitable and desirable, see the world as involving competition between groups, pursue activities and professions that tend to enhance intergroup hierarchy, and exhibit bias toward a range of other groups.

FUNCTIONAL INTERDEPENDENCE AND INTERGROUP RELATIONS

Whereas social categorization and individual difference approaches to understanding intergroup relations focus on how the motivations and orientations of people, independent of the actual relationship between groups, can produce negative intergroup relations, other psychological and sociological perspectives emphasize that the nature of intergroup relations is shaped substantially by the functional relationship between the groups. Specifically, cooperation between groups, particularly when it has successful consequences, fosters positive intergroup relations; competition between groups, whether for material resources or intangible qualities such as status, promotes prejudice and discrimination.

Theories based on functional relations often point to competition and consequent perceived threat as a fundamental cause of intergroup prejudice and conflict. Realistic group conflict theory, for example, posits that perceived group competition for resources produces efforts to reduce the access of other groups to the resources. Individual differences, such as the tendency to see intergroup relations as zero-sum (i.e., when one group gains, the other automatically loses), which is associated with people high in social dominance orientation, can amplify the effects of competitive group functional relations, producing particularly adverse effects on intergroup relations.

The functional relationship perspective also emphasizes how changing the nature of intergroup interdependence can substantially alter intergroup relations. In the classic Robber's Cave study, for example, two groups of boys at a summer camp first developed their separate group identities through a series of collective activities, unaware of the presence of the other group. When the two groups of boys were brought together under competitive circumstances, negative intergroup relations developed. The boys not only called each other names but also engaged in hostilities. Simply bringing the groups together did not improve intergroup relations; in fact, it intensified conflict. However, more harmonious intergroup relations were created when the groups worked together to attain superordinate goals (objectives that both groups desired but that could be achieved only jointly through cooperation) and their combined efforts were successful.

Group status is another aspect of the functional relationship between groups that influences intergroup relations. In general, members of high-status groups view intergroup relations as more favorable than do members of low-status groups. In part as a consequence, members of low-status groups, particularly when they see the status difference as illegitimate and unstable, are more motivated to alter the relationship between the groups than are members of high-status groups. High-status groups, in contrast, tend to endorse and promote system-justifying ideologies, which are sets of beliefs (e.g., stereotypes about the different characteristics of women and men) that legitimize, and thus reinforce, the role and status differences between the groups.

The impact of functional relations on intergroup orientations occurs, in part, by influencing social categorization processes. For example, whereas

competition between the groups of boys at the summer camp intensified the distinction between the in-group and out-group, between *us* and *them*, cooperation to achieve the superordinate goal led them to see each other as members of a common in-group. Thus, social categorization, individual difference, and functional relationship approaches can be seen as complementary perspectives rather than as alternative, competing positions. Understanding these processes also contributes to developing effective interventions for improving intergroup relations, such as the contact hypothesis.

INTERGROUP CONTACT AND INTERGROUP RELATIONS

For more than 50 years, the contact hypothesis has represented psychologists' most popular and effective strategy for promoting harmonious intergroup relations. This hypothesis proposes that simple contact between groups is not sufficient to improve intergroup relations. For contact between groups to reduce bias successfully, the contact must involve equal status between the groups, cooperative (rather than competitive) intergroup interaction, opportunities for personal acquaintance between the members, especially with those whose personal characteristics do not support stereotypic expectations, and supportive norms by authorities within and outside the contact situation. These conditions of intergroup contact are prominent elements of specific strategies for improving intergroup relations, such as cooperative learning and jigsaw classroom interventions, in which students are interdependent on one another in problem-solving exercises.

Several different processes, related to both the functional relationships between groups and social categorization, contribute to the positive effect of appropriately structured intergroup contact on intergroup relations. For example, cooperation can induce greater intergroup acceptance because of dissonance reduction serving to justify this type of interaction with the other group. Also, when intergroup contact is favorable and productive, the rewarding properties of achieving success may become associated with members of other groups, thereby increasing attraction and reducing intergroup anxiety.

Intergroup contact can also influence how people conceive of the groups and how the members are socially categorized. Close and personalized interaction between members of different groups can induce

people to think of others more in terms of their personal identity than as members of another group, thereby weakening the in-group–out-group distinction. Cooperative, equal-status interaction between groups can induce people to reconceive of themselves primarily as one common group, which can redirect the forces of in-group favoritism to improve attitudes toward others previously seen only in terms of their out-group membership. Moreover, developing a common group identity does not require people to abandon their separate group identities entirely. Retaining original group identities, but in a context that emphasizes cooperation (e.g., art students and science students working together on a task that requires both types of skills) or within a complementary common identity (accountants and marketers within the same company), can reduce threat to original group identity while creating more positive intergroup relations.

SUMMARY

Intergroup relations are determined critically by how people socially categorize others, by perceptions shaped by personal needs and values, and by the actual functional nature of the relationship between groups. These processes typically operate in concert. In part because the mere categorization of people into groups is sufficient to initiate intergroup bias, research in this area has typically focused on how to reduce intergroup bias and conflict. Nevertheless, the principles of social categorization, social identity, contact, superordinate goals, and functional interdependence may be applied initially in intergroup contexts to promote positive and constructive intergroup relations. Under these conditions, the unique contributions of the different groups can be recognized and appreciated, and the efforts of the members of the different groups can be coordinated to achieve mutually desirable goals.

INTERPERSONAL COMMUNICATION

Interpersonal communication is a dynamic and complex human phenomenon that includes at least two communicators. These communicators intentionally orient toward each other as both subject and object whose actions embody each other's perspectives both toward self and toward other. In essence, interpersonal communication is a goal-driven interaction between at least two people that typically occurs in a face-to-face environment. However, scholarly trends are moving toward studying mediated interpersonal communication via communication technologies. Interpersonal communication in organizations represents an interaction process including a variety of relational situations. These internal situations involve superior–subordinate and peer communication. This article centers on internal interpersonal communication. First, an overview of the process of interpersonal communication will be provided. Second, interpersonal communication is situated in organizations by examining superior–subordinate communication and peer communication. Finally, the process of interpersonal communication is contextualized by reviewing the impact of trust

and technology on interpersonal communication in organizations.

THE PROCESS OF INTERPERSONAL COMMUNICATION

The process of interpersonal communication is viewed from a general communication perspective provided by Claude Shannon and Warren Weaver. This model, in its most basic format, includes the sender, the message, the channel, and the receiver. Noise provides an additional component.

The first two components of interpersonal communication are the sender and the message. The sender mentally composes a message to relay to another person, taking into account the reason, or intention, for sending the message. Perhaps it is meant to persuade, or to inform. The act of transferring this message from thought to words is called *encoding*.

The *channel* in this model refers to the mode of communication used to relay the message. Familiar channels include television, radio, and newspaper. However, interpersonal communication differs from mass communication in this respect because the channel used is face-to-face communication in which messages are relayed through verbal interaction at one location.

The fourth component of this model is the receiver. This person is responsible for taking the sender's message and decoding it. The action of decoding results in the assignment of meaning by the receiver.

The exchange described is one basic unit of interaction between communicators. Once the receiver decodes the message and gives meaning to it, that person can encode another message to relay to the sender. The resulting action is characterized as *feedback*. Feedback helps to clarify the original message or to enhance it. In the feedback process, the original receiver then becomes the sender who encodes the message, and the original sender becomes the receiver who decodes the message. Again, the channel of communication remains face-to-face. This process can continue in a cyclical manner, creating a dialogue between both people.

An additional component affecting the interaction represented in this model is noise. *Noise* refers to anything that could interfere with the transmission of the message from the sender to the receiver, and it can be attributed to a number of sources. Physical sources are often much easier to recognize and would include a

loud truck driving by while the sender was talking to the receiver during a meeting, or if the receiver was having difficulty with his hearing aid while listening to the sender speak.

Noise related to differences in perception can also interfere with the ability for communicators to relay a message. This type of noise is attributed to a number of factors, including nonverbal communication and cultural differences. Differences in perception can lead to conflict among the communicators.

SUPERIOR-SUBORDINATE COMMUNICATION

The supervisory-subordinate relationship is the primary interpersonal relationship structured by the organization. Individuals' relationship with their supervisor is one of the most important communication facets of their organizational life. This relationship is so critical that it may determine how individuals identify with the organization, as well as the individuals' job and organizational satisfaction and commitment. Particularly, the quality of supervisory communication and information exchanges have been linked to revenue and productivity measures of the overall organization.

Most organizations typically have superior-subordinate relationships among organizational members. Generally, research in the area of superior-subordinate interpersonal communication centers on exchanges of information and influence between organizational members, at least one of whom has formal authority, granted by the organizational structure, to direct and evaluate the activities of other organizational members. Daniel Katz and Robert Kahn suggested that superior to subordinate communication typically centers on information regarding organizational procedures and practices, indoctrination of goals, job instructions, job rationale, or feedback on performance. Similarly, subordinate to superior communication typically focuses on information about the subordinates themselves, their colleagues, and their work-related or personal problems; information about tasks to accomplish; or about organizational policies and practices.

A. F. Smith and S. A. Hellweg found in 1985 that subordinates are more satisfied with their work when communication between subordinate and supervisor is good. A strong predictor of subordinate satisfaction is the superior's ability to listen, respond quickly to messages, and be sensitive, empathic, and understanding.

V. R. Waldron and M. D. Hunt further posited in 1992 that subordinates reporting high-quality relationships with their supervisors were more likely to engage in informal, friendly interactions with their supervisors, to conform to formal and informal requests, to attempt to clarify expectations, and to accept criticism from supervisors than were individuals reporting lower-quality relationships.

Leader–member exchange (LMX) theory frequently informs superior–subordinate relationships. The LMX theory has been linked to a variety of communication behaviors and suggests that leaders have limited time and resources and share both personal and positional resources differently with their subordinates. In sum, Jaesub Lee and colleagues suggested in 1999 that leaders tend to develop and maintain exchanges with their subordinates that vary in degrees of quality. These relationships range from high (in-group) to low (out-group) exchanges. In-group exchange is considered a high-quality relationship reflected by high levels of information exchange, mutual support, informal influence, and trust, and greater negotiating latitude and input in decision influence. Alternatively, out-group exchange reflects a low-quality relationship characterized by formal supervision, less support, and less trust and attention from the supervisor.

RESEARCH ON SUPERIOR–SUBORDINATE RELATIONSHIPS

There are several areas of research examining issues of superior–subordinate communication. These include the following:

- **Interaction patterns.** Research that studies the communication patterns between supervisors and their subordinates. How much time is spent communicating with each other? Who initiates the communication? What is the importance of the interactions?
- **Openness in communication.** This line of research examines two dimensions of openness in the superior–subordinate relationship: message sending (delivering bad news, candor in communication, providing important company facts) and message receiving (encouraging frank expressions of alternative views).
- **Upward distortion.** This occurs when persons of lower hierarchical rank in organizations communicate with persons of higher rank. Upward distortion falls into four general categories:

1. Subordinates tend to distort upward information, saying what they think will please their supervisors.
 2. Subordinates tend to filter information and tell their supervisors what they, the subordinates, want them to know.
 3. Subordinates often tell supervisors what they think the supervisor wants to hear.
 4. Subordinates tend to pass personally favorable information to supervisors while not transmitting unfavorable information about themselves to supervisors.
- **Upward influence.** This line of research focuses on two dimensions of influence: (a) the effects a superior's influence in the hierarchy has on his or her relationships with subordinates and (b) subordinates' use of influence with their supervisors.
 - **Semantic-information distance.** This research describes the gap in agreement and/or understanding on specific issues between superiors and subordinates (e.g., job duties and leaders' authority).
 - **Effective versus ineffective superiors.** Examines prescriptive characteristics of effective and ineffective communication behaviors among organizational supervisors, as well as communication qualities of effective leaders.
 - **Personal characteristics.** These study the mediating effects of personal characteristics of superiors and subordinates (e.g., communication apprehension, communication competence, locus of control, and communicator style).
 - **Feedback.** Research focusing on relationship between feedback and performance, feedback and motivation, feedback and attributional processes, the use of rewards and punishments as feedback, and the feedback-seeking behavior of individuals.
 - **Conflict.** Research examining the role of communication in superior–subordinate conflict (e.g., conflict management style, organizational level, power, perceptions of skills, perceptions of subordinate's personality).

Peer Communication

Peer communication is an important interpersonal facet in everyday organizational life. This area of study focuses on coworker communication within and between work groups. Peer communication is important for three reasons:

1. Peer interpersonal communication differs from superior–subordinate communication (e.g. relationship rules, message strategy choices).

2. Peer communication and the use of groups to accomplish work goals in organizations is increasing.
3. Peer interpersonal communication is an important source of support, friendship, and job satisfaction and commitment.

Peers communicate about job requirements, provide social support, and are in a position to give advice without formally evaluating performance. Peers also may help each other solve organizational problems or issues and utilize the best strategies to use with supervisors. However, peer communication is not without problems. Peers can withhold information from one another, which makes accomplishing individual and group goals difficult.

Research on Interpersonal Communication in Organizations

Interpersonal communication is complex. It is a difficult proposition to communicate effectively with others while maintaining an authentic sense of self. Communication may be difficult with others owing to the wide array of interactions on a regular basis. Communication partners have different interpersonal communication experiences that contribute to how they communicate and interact with others. Exposure to multiple communication partners can be confusing if one is not familiar with recognizing and adjusting to different styles and patterns of communication.

Several factors contribute to the interpersonal communication process in organizations. They include interpersonal trust, the use of nonverbal communication, cultural differences between the partners, and technology in interpersonal relationships.

Interpersonal Trust in Organizations

The role of interpersonal communication in the development of relationships is a popular area of study for communication researchers. Interpersonal communication may occur between people who have had continual interaction or between people who do not have past experiences with each other, allowing a reduction in drawing on a historical frame of reference. Regardless of the interpersonal situation, trust is a critical factor in all interpersonal relations. Although a general term, *trust* is defined as positive expectations about the behavior of others based on roles, relationships, experiences, and interdependencies, as noted by

Pamela Shockley-Zalabak in 2002. Shockley-Zalabak, Kathleen Ellis, and Ruggero Cesaria discussed in 2000 the central role that organizational communication plays in the behavior components of trust. These scholars highlight three primary areas of organizational trust that strengthens communication:

1. *Accurate information.* Information flow that is forthcoming
2. *Explanations for decisions.* Adequate and timely feedback on decisions
3. *Openness.* Managers and supervisors freely exchange thoughts and ideas with their employees

TECHNOLOGY AND INTERPERSONAL COMMUNICATION

Interpersonal communication is typically restricted to communication that occurs in a face-to-face environment. However, with an increase in the use and access of technologies in organizations, mediated interpersonal communication is becoming a salient area of inquiry. Knowledge of interpersonal communication has become more important in recent years, especially as organizations have expanded their activities to other countries and relied on computer-mediated communication to overcome physical distances. The rapidly increasing use of computer-mediated communication to connect members of an organization has resulted in more research relating to both computer-mediated communication and globalization. It raises questions regarding key assumptions of face-to-face interaction and highlights the need to understand interpersonal communication. This higher level of awareness is more likely to produce organizational members who recognize their own and others' communication needs, resulting in communicators who are more effective.

Technology is changing the way we view and engage each other in our relationships. Communication technologies have eradicated boundaries of brick-and-mortar buildings, where face-to-face interactions were predominant, to expand time and spatial restrictions that inform interpersonal and work communication. Individuals accomplish work through various time zones, cultural differences, and particularly geographic locations. Because of this, we work with people without much information about their background, history, or experiences, much less their worldviews, values, and ideology. This may create

opportunities for effective interpersonal communication or may greatly hinder it, depending on how well individuals react to this new way of working. Teleworking (individuals who work at home or in other organizationally controlled spaces) and virtual teams (individuals who work as part of a team remotely solely using communication technologies) are new interpersonal communication configurations informed by technology.

INTERPERSONAL COMMUNICATION STYLES

Interpersonal communication style is the manner in which one communicates. It includes the way one interacts to create expectations for future behavior on the part of both participants. *Communication* is the transmission of information and meaning from one individual to another. The communication process, whether verbal or nonverbal, involves a sender and a receiver. Whether we realize it or not, people are constantly shaping our behavior by the ongoing style they use as they talk to us.

INTERPERSONAL COMMUNICATION STYLE RESEARCH

Scholars have extensively studied communication styles in interpersonal relationships. Research in this area has primarily focused on the effect of gender on communication style, the relationship between the communicators and its effect (i.e., type of relationship and length of time, supervisor and subordinate), culture, situation, and the expectations of communicators. Also, research on the effect of mediated communication on communication styles as it relates to interpersonal communication is of recent interest.

DESCRIPTIONS OF INTERPERSONAL COMMUNICATION STYLES

Robert Norton developed nine specific communicator styles typically used in the communication process that inform the nature of the relationship between communicators. These styles have been studied extensively in several organizations to assess communication satisfaction and commitment.

- **Dominant communication style.** The dominant style of communication is characterized by speaking frequently, strongly, in a dominating and take-charge manner. Communicators using a dominant style are

often perceived by others as individuals who possess high levels of self-confidence. This perception is reinforced by their willingness to speak often in a conversation using a strong and steady voice, as well as their ability to control the environment in which the communication occurs. Communicators who prefer this style also rely on the use of body language including recurring eye contact and the negotiation of others' personal space to emphasize communicative dominance.

- **Dramatic communication style.** This style of communication requires the communicator to merge both physical and verbal techniques to create a performance of the message. Communication using this style is often accomplished through storytelling, the application of jokes, and the use of hyperboles. The actual meaning of a dramatic communicator's message may be hidden and could require background knowledge of the communicator to uncover it. Communicators may use this style to deal with negative information they cannot convey to someone else at face value. Other reasons for selecting a dramatic style of communication are to reinforce a communicator's status in the group or to alleviate stress among group members.
- **Contentious communication style.** This style of communication is similar to a dominant style of communication. Communicators using a contentious style of communication are often described as being argumentative. People who use this style are not afraid to challenge others, especially if they have evidence to support their position. Consequently, they expect their communication partners to present similar substantiation when making a claim. Contentious communicators are very precise about the words they use and view communication as being straightforward without any area for delineation. Individuals interacting with someone who uses this style may feel the need to defend themselves, which may result in less focus on the message.
- **Animated communication style.** Animated communicators typically reveal more about their thoughts and emotions through body language than through verbal communication. When interacting with communication partners, people who use this style rely heavily on facial expressions to convey meaning. Some of these expressions include eye contact to show interest in a communication partner or to reveal emotions, smiling to show pleasure, and nodding to show support or agreement. Communicators using an animated communication style also gesture frequently, using their hands in addition to posture and body positioning to indicate thoughts.
- **Impression-leaving communication style.** This communication style is somewhat difficult to distinguish from others because it relies heavily on the impression formed of the sender by the receiver. People who use this style deliver messages in a manner that is unique and easy for receivers to differentiate from other communication partners. This quality makes people using an impression-leaving style easy to remember. It is possible that people who use an impression-leaving style could use another style but communicate in such a way that differentiates them from other people who use that style.
- **Relaxed communication style.** Communicators who approach communication in a relaxed style appear calm when interacting with their communication partners, even in high-stress situations. This demeanor often provides reassurance to their partners because they do not appear anxious and can make others feel comfortable. Relaxed communicators speak in a natural but confident manner and do not seem to be nervous when observed by communication partners.
- **Attentive communication style.** This communication style is characterized by the actions of the sender rather than the verbal communication of that person. Someone who has an attentive communication style is a good listener and lets communication partners know they are being heard. Body language such as eye contact and nodding let communication partners know that the attentive communicator is listening. People who use this style of communication are often regarded as empathetic and are able to internalize their partner's message, which is one reason that communication partners tend to open up to them.
- **Open communication style.** People who use an open style of communication are not afraid to express their thoughts and emotions and will generally let others know how they feel. Open communicators reveal personal information rather quickly when interacting with communication partners, with little regard to the potential outcome. Adjectives used to describe this type of communicator are *talkative*, *approachable*, and *conversational*. An open communication style could be considered a positive or a negative attribute and would depend a great deal on the communication partner's perception.
- **Friendly communication style.** Communicators who use a friendly style of communication have a positive effect on their communication partners. This effect results in people seeking interaction with them. Friendly communicators use both body language and verbal communication to reinforce the self-image of others by showing them that they

attract people who are friendly. This style of communication is also characterized by the recognition of the accomplishments and value of communication partners.

SUMMARY

Communication styles are an essential factor in studying interpersonal communication. Communicators may use different communication styles in different situations but generally rely on a particular style because they are comfortable using it. Factors affecting communication style include the relationship of the communication partners, social norms, and the specific organizational situation.

INTRINSIC AND EXTRINSIC WORK MOTIVATION

Intrinsically motivated people engage in an activity because they experience it as interesting and enjoyable. Intrinsic motivation is the prototype of autonomous motivation, for people engage in the activity with a sense of self-initiation, freedom, and volition. In contrast, extrinsically motivated people engage in the activity because it is instrumental to a separate, though desirable consequence—for example, attaining a reward or avoiding a punishment. With extrinsic motivation, satisfaction comes not from the activity itself but, rather, from the extrinsic consequences to which the activity leads. Research has shown that optimal challenge, positive performance feedback, and choice about activities stimulate interest and

enhance intrinsic motivation. In contrast, contingent rewards, surveillance, and threats highlight contingencies that enhance extrinsic motivation.

Although some motivation theories argue that intrinsic and extrinsic motivation have additive effects on performance and satisfaction, research has shown that the two types of motivation tend to interact. Specifically, when extrinsic rewards are offered to a person for doing an intrinsically motivated activity, the rewards can either enhance or diminish the person's intrinsic motivation. In particular, tangible rewards have been found to decrease intrinsic motivation. This often-replicated finding led many writers to assert that intrinsic and extrinsic motivation are invariantly antagonistic. Self-determination theory (SDT) makes clear, however, that the two types of motivation tend to be compatible when the extrinsic motivation has been well internalized.

THE SELF-DETERMINATION CONTINUUM

Self-determination theory proposes that extrinsic motivation varies in the degree to which it is autonomous depending on the degree to which it has been internalized. Activities that are not interesting (i.e., that are not intrinsically motivating) require extrinsic motivation, so their initial enactment depends on the perception of a contingency between the behavior and a consequence such as the manager's approval or a tangible reward. When so motivated, the activity is said to be *externally regulated*—that is, initiated and maintained by contingencies external to the person (e.g., I work hard because I will be rewarded for doing so). This is the classic type of extrinsic motivation that was found to undermine intrinsic motivation, and it is the prototype of being controlled—that is, of being pressured to behave, think, or feel a particular way.

External regulations can, however, be internalized, in which case the external contingencies are no longer required and people continue to work even when the boss is not watching. According to SDT, there are three different degrees to which a regulation and its underlying value can be internalized. The least complete form of internalization is referred to as *introjection*, in which people take in a contingency without accepting it as their own. Thus, it is as if the contingency, which is now internal, still controls them. For example, when people behave so others will acknowledge them, they are externally regulated, but when they introject the regulation they behave to feel like a

worthy person—that is, to experience the self-esteem that has become contingent on the behavior. Another example of introjected regulation is behaving to protect an ego involvement. Introjected regulation, although internal to the person, is still a *controlled* form of extrinsic motivation because people feel pressured to behave by the introjected contingency.

When people *identify* with a regulation, they engage in an activity because it is congruent with personal values, goals, and identities. Through identification, they accept the regulation as their own and feel greater freedom and volition. A day care worker who strongly values children's comfort, growth, and well-being and who understands the importance of doing the unpleasant tasks that foster the children's well-being would feel relatively autonomous when changing dirty diapers or cleaning up vomit.

Finally, if a regulation were *integrated*, people would have a full sense that the behavior is an integral part of who they are. This type of regulation would result when an identification has been integrated with other aspects of the person's self—that is, with other identifications, interests, and values. The day care worker would not only have identified with the importance of the unpleasant aspects of caring for the children, but would have accepted the job as an integral part of his or her life and would even be more likely to do unpleasant tasks that helped other children. Integrated regulation represents the most autonomous form of extrinsic motivation. However, it is not the same as intrinsic motivation, because intrinsic motivation is characterized by being *interested* in the activity itself, whereas autonomous extrinsic motivation is characterized by the activity being *instrumentally important* for personal goals or values.

The different types of regulation can be aligned along an autonomy continuum ranging from *amotivation*, which means that the person is not motivated and thus is wholly lacking in autonomy, through the four types of extrinsic motivation (i.e., external, introjected, identified, and integrated, which, respectively, represent increasing autonomy), to intrinsic motivation, which is the most autonomous type of motivation. This autonomy continuum does not, however, mean that SDT is a stage theory, nor does it imply that people must invariantly move through the regulations sequentially for a particular behavior. Rather, the degree of internalization depends on aspects of the person, the task, and the context within which the person engages the task.

Conceptualizing extrinsic motivation in terms of internalization effectively changed the central distinction in motivation from intrinsic versus extrinsic to autonomous versus controlled. Intrinsic motivation and identification/integration constitute autonomous motivation, whereas external and introjected regulation constitute controlled motivation.

In organizational settings, workers' motivation can be assessed with an instrument that asks, for example, why they try to do well at their job. Various reasons are then presented that reflect the types of motivation. Participants rate the degree to which each is true for them. Examples of reasons offered include the following: for external reasons, so as not to upset the boss; for introjected reasons, to feel like a good person; for identified and integrated reasons, to fulfill personal goals and values; for intrinsic reasons, to experience interest and enjoyment; and for amotivation, not trying or knowing why. Research has supported the control-to-autonomy continuum by showing that each type of motivation correlates most positively with the other types located closest to it on the continuum and less positively or more negatively with types located farther from it.

AUTONOMY AND THE SOCIAL CONTEXT

Considerable work has examined aspects of the social context that enhance versus undermine autonomous motivation. Some studies have examined effects of the social context on intrinsic motivation, whereas others have examined contextual effects on internalization. Dozens of studies led to the SDT proposition that people have three basic psychological needs—for competence, autonomy, and relatedness—and that contextual factors that provide satisfaction of these needs enhance autonomy, and those that thwart satisfaction of the needs diminish autonomy and promote either controlled regulation or amotivation.

Significantly, various studies have also shown that satisfaction of the basic needs promotes more effective job performance, better learning, greater persistence at difficult tasks, enhanced engagement with a job, more positive work attitudes, decreased stress, and better adjustment and well-being. These findings have emphasized the importance of examining the factors that promote autonomy through support for the basic psychological needs.

Laboratory experiments have shown that external factors such as tangible rewards, deadlines, surveillance,

and evaluations tend to thwart the need for autonomy and undermine intrinsic motivation, and negative feedback tends to undermine intrinsic motivation by thwarting the need for competence. In contrast, external factors such as acknowledging feelings and providing choice tend to enhance feelings of autonomy and increase intrinsic motivation, and positive feedback tends to increase intrinsic motivation by enhancing feelings of competence.

Of course, intrinsic motivation in the workplace is very important, but intrinsic motivation requires that work activities be interesting—for example, that there is variety or challenge to the work and that there are opportunities to make choices or decisions relevant to the job. When work activities cannot be made more interesting, internalization of extrinsic motivation becomes the critical issue. Significantly, internalization also occurs when the work environment allows satisfaction of the basic needs.

Of significance to industrial/organizational psychologists, research has shown that work climates, managerial approaches, and leadership styles that support employees' competence, autonomy, and relatedness—for example, by encouraging self-initiation, problem solving, group interaction, and collective responsibility—promote employees' identification and integration of extrinsic motivation. Additional work-climate factors that have been found to facilitate internalization are providing a *meaningful rationale* for doing an uninteresting behavior and *acknowledging feelings* about the various aspects of the jobs. Facilitating internalization is important in organizations because autonomous extrinsic motivation is more predictive than intrinsic motivation of behaviors that are not interesting and require discipline or determination.

When a job involves only simple and repetitive tasks, there is typically not a performance advantage to autonomous relative to controlled motivation, but even in those situations, autonomous motivation is associated with greater job satisfaction and well-being. This implies that, overall, autonomous motivation is preferable in organizations because even with boring jobs, there is an advantage to autonomous motivation for job satisfaction and well-being, which are likely to yield better attendance and lower turnover.

REWARDS AND MOTIVATION

As mentioned earlier, studies have shown that tangible rewards tend to have a detrimental effect on intrinsic motivation, and a meta-analysis of more than

100 studies confirmed this effect. Verbal rewards (i.e., positive feedback), on the other hand, were found to enhance intrinsic motivation. The meta-analysis also found limiting conditions to the negative effects of tangible rewards. When rewards were given independent of specific task engagement (as might be the case with a salary), or when the rewards were not anticipated (as might be the case with unexpected bonuses), tangible rewards did not significantly undermine intrinsic motivation. The conditions under which rewards were most likely to negatively affect intrinsic motivation were when people expected them while working on a task and when the rewards were contingent on doing the task or performing well at it. When rewards were contingent on performing well, they tended not to be as detrimental as when they were contingent just on doing the task or completing it. This is because the positive feedback inherent in rewards that are given for performing well enhances people's feelings of competence, and that tends to offset some of the negative effect of rewards that is caused by the thwarting of autonomy.

Some studies have gone further to show that when rewards are administered *informationally*—that is, when they signify competence, convey appreciation, and acknowledge the person's initiative in doing a good job—they can have a positive rather than negative effect on intrinsic motivation. However, creating these rewarding conditions tends to be quite difficult. Furthermore, if positive feedback (without being accompanied by tangible rewards) is administered informationally, it leads to greater intrinsic motivation than informationally administered performance-contingent rewards that implicitly convey the same positive feedback. Thus, one can conclude that, although the use of tangible rewards may at times have a positive effect on intrinsic motivation when administered as a nonpressured expression of appreciation for a good job, informationally administered positive feedback appears to be an even more powerful means of maintaining and enhancing people's intrinsic motivation on the job.

Because intrinsic motivation is associated with better performance than controlled extrinsic motivation, the undermining of intrinsic motivation by extrinsic rewards is negative for organizational effectiveness. Research has shown that contingent tangible rewards and other extrinsic factors, such as competition and evaluations, can be detrimental to outcomes such as creativity, cognitive flexibility, attaining difficult goals, problem solving, and well-being. For example, a negative relation between the perception of extrinsic

rewards and the amount of intrinsic motivation was found in one study, and another study found that the introduction of a merit-pay program led to workers' feelings of decreased autonomy and intrinsic motivation. Still another found that pay-for-performance plans led to lower well-being in blue-collar workers who had monotonous jobs. Moreover, one meta-analysis showed that programs using financial incentives had smaller positive effects than did programs using training and goal setting.

Taken together, the various results have three implications for organizations. First, unexpected bonuses may not be undermining, but unexpected bonuses must be used very sparingly or they will soon be expected. Second, salaries, which do not emphasize links between specific behaviors and rewards, are less likely to undermine intrinsic motivation than are pay-for-performance systems. Indeed, it is best to keep rewards relatively nonsalient in organizations rather than to think of them as a central means of motivating employees. People need to feel that they are being equitably rewarded, but using rewards as a central motivational strategy is likely to backfire. Third, if contingent rewards are to be used, it is important that they be used to acknowledge good performance and that they be given in an informational way. This will minimize people's feelings of being controlled and will reduce the negative effects of the rewards on performance and well-being. In short, rewards are an important aspect of organizational life, but the research indicates that reward structures in organizations are likely to be most effective when they are not used as a means of motivating specific behavior.

ITEM RESPONSE THEORY

Item response theory (IRT), also called latent trait theory, is a psychometric theory that was created to better understand how individuals respond to individual items on psychological and educational tests. The underlying theory is built around a series of mathematical formulas that have parameters that need to be estimated using complex statistical algorithms. These parameters relate to properties of individual items and characteristics of individual respondents. The term *latent trait* is used to describe IRT in that characteristics of individuals cannot be directly observed; they must be inferred by using certain assumptions about the response process that help estimate these parameters.

Item response theory complements and contrasts classical test theory (CTT), which is the predominant psychometric theory taught in undergraduate and graduate programs. Classical test theory differs from IRT in several ways that will be discussed throughout this entry. In general, though, IRT can be thought of as analogous to an electron microscope for item analysis, whereas CTT would be more like a traditional optical microscope. Both techniques are useful for their own purposes. Just like the electron microscope, IRT provides powerful measurement analysis; IRT is useful if you have a need for specific, precise analysis. On the other hand, CTT can be just as useful as IRT when the research questions are vague and general. In medical research, sometimes the optical microscope is preferred to the electron microscope. Likewise, CTT may be preferred in some situations.

THE ITEM RESPONSE FUNCTION

Item response theory relates characteristics of items and characteristics of individuals to the probability of affirming, endorsing, or correctly answering individual items. The cornerstone of IRT is the *item response function* (IRF), which is the graphical representation

Figure 1 Graphical Representation of a Hypothetical Item Response Function

of a mathematical formula that relates the probability of affirming item i with the value of a latent trait, θ . Figure 1 presents a graphical representation of a hypothetical IRF.

In Figure 1, the x -axis relates to the level of the characteristic being measured by the test. This trait, θ , is typically scored like a z score, with scores at zero being average and scores above zero being above average; scores below zero are below average. Typical θ distributions range from -3 to $+3$. The y -axis relates to the probability of affirming an item. For ability items, the y -axis measures the probability of answering an item correctly. For items without correct answers (e.g., attitude or personality items), the y -axis refers to the probability of choosing the keyed option (i.e., the option that taps high conscientiousness). The IRF relates the level of θ with probability of affirming the item. As can be seen in Figure 1, as θ increases, the probability of affirming the item also increases. This property of monotonicity is common with IRT models. As can be seen in Figure 1, an individual with a $\theta = 0$ would have an expected probability of affirming the item of roughly 50%. The corresponding probabilities for a person of $\theta = -3$ and $\theta = +3$ are roughly 0% and 100%, respectively.

There are many different forms of the IRF. For dichotomously scored items (e.g., right versus wrong or true versus false), the two-parameter logistic model (2PL) and the three-parameter logistic model

(3PL) are commonly used. The formula for the 3PL model is

$$P(u_i = 1 | \theta) = c_i + (1 - c_i) \frac{1}{1 + e^{-1.7a_i(\theta - b_i)}} \quad (1)$$

where the probability that a person with a latent trait, θ , affirms an item i (i.e., $u_i = 1$) is a function of three parameters: a_i , a discrimination parameter; b_i , a location parameter; and c_i , a pseudo-guessing parameter. The probability of affirming items with large a parameters varies sharply as a function of θ , whereas the probability of affirming items with low a parameters varies weakly as a function of θ . Mathematically, the a parameter determines the slope of the IRF at its most discriminating point. Items with low a parameters are generally considered poor, undiscriminating items. Items with large, positive b parameters will be endorsed only by respondents with large, positive θ s, whereas items with large, negative b parameters will be endorsed by everyone except people with the most extreme negative θ s. With ability tests, items with large positive b parameters are judged to be difficult, whereas those items with large negative b parameters are judged to be easy. With items that do not have correct answers, the b parameter is often called a *location* or *threshold* parameter. The c parameter introduces a nonzero lower asymptote to the IRF so that respondents

with large negative θ s will have a nonzero probability of affirming the item; this nonzero asymptote may result from guessing or other processes.

The 2PL formula is a submodel of the 3PL and can be obtained by setting the c parameter to zero. This model has the implicit assumption that people with the lowest θ values will have a zero probability of affirming the item. The 2PL model is useful in situations, such as personality measurement in a research setting, in which there should be little or no guessing involved. An even simpler model, the Rasch model, is obtained by setting the a parameter to be constant across all items. Each of these models assumes that each item is measuring only one θ dimension. In general, it is best to choose the simplest model (i.e., the one with fewest parameters), given the typical sample sizes that industrial/organizational psychologists face. Simpler models make the most efficient use of data. By plotting the IRFs, researchers can compare the functioning of items, determine the extent of guessing, and determine the range of θ that the item is most discriminating.

Other, more complex models exist to measure more complicated types of data. Polytomous IRT models can be used to model data that have more than two scored options. These models replace the IRFs with option response functions (ORFs). Instead of characterizing an item with just one function, an item, as modeled with a polytomous IRT model, has an ORF for each option. Therefore, a five-option item would have five different ORFs. With ORFs, the x -axis still measures θ , whereas the y -axis then becomes the probability of choosing each particular option. There are different polytomous IRT models that have differing assumptions. Some models work with ordinal data, and assume that option 1 has a more negative threshold than does option 2, which in turn has a more negative threshold than does option 3. This assumption would be appropriate for Likert-scale-type data. Other, more flexible models do not make assumptions about the ordering of options. These models might be more appropriate in cases, such as multiple-choice exams, in which it would be difficult to determine a priori the rank ordering of options. Besides polytomous IRT models, other models exist that allow for nonmonotonic functions, as well as for multiple dimensions of θ to affect responses. New IRT models are introduced on a frequent basis. Often, however, newer complex models are difficult to estimate without prohibitively large data sets.

APPLICATIONS OF ITEM RESPONSE THEORY

Item response theory has had a significant impact in psychology by allowing for more precise methods of assessing properties of tests compared with classical test theory. In addition, IRT has had a big impact on psychology by making possible several tools that would be difficult to create without IRT. Psychometric applications, such as computerized adaptive testing, detecting item bias, equating tests, and identifying aberrant individuals, have been greatly improved with the development of IRT. In particular, computerized adaptive testing merits additional discussion.

Computer adaptive tests work by choosing items that are best suited for identifying the precise level of θ for an individual respondent. Specially, there is an IRT concept called *information* that is important for adaptive tests. Item-level information is related to the amount of uncertainty about a θ estimate that can be reduced by administering that item. Information differs by the level of θ . Some items will have high information for low levels of θ , whereas other items may have high levels of information for high levels of θ . Imagine a mathematics test. A basic algebra item may provide high amounts of information for people who possess extremely low ability. That same item, however, would do little to differentiate between individuals of moderate and high math ability. To differentiate between those individuals, a more complex item would need to be given. Information functions can be plotted for individual items (or for tests) to see for what level of θ the item is best suited.

Computerized adaptive tests work by choosing items that have large amounts of information for the respondent's estimated θ . Theta estimates are revised after each item response, and then a computer algorithm selects the next item to present based on the information level of items at the revised theta estimate. By choosing only items with large amounts of information, adaptive tests can maintain measurement precision at the levels of conventional tests even though fewer items are administered.

Item response theory has already had a major effect on educational testing through its impact on computerized adaptive testing (CAT). In the 1990s, Educational Testing Service implemented a CAT version of the Graduate Record Examination (GRE). The success of adaptive testing would not be possible without development of IRT. Large-scale adaptive testing would not be possible using CTT.

In the future it is likely that item response theory will yield progress, not only in improvement of measurement technologies but also by making contributions in substantive areas, such as decision-making theory. Graduate students, researchers, and practitioners who are interested in psychological measurement should invest some time to learn more about IRT technology. Computer programs, such as BILOG, MULTILOG, and PARSCALE, are available to conduct IRT analyses.

JOB ADVERTISEMENTS

Job advertisements are mechanisms used by organizations to communicate employment need. Globally, job advertisements are commonly used by all types of organizations and represent the most prominent form of early contact job seekers have with employers. On any given day, newspapers, magazines, and Web sites feature ads extolling the virtues of employment in millions of jobs. Across different channels of communication, job advertisements can take many forms, from colorful full-page ads in a business magazine to the more traditional classified entries found in newspapers.

The impact of job advertisements depends on the framing and quality of their content, and their impact is often debated in the research literature and among practitioners. Specifically, employers typically find that job ads yield relatively fewer quality applicants than other recruitment sources, but the value of such ads extends beyond the context of employment communication. Because of this extended value, a discussion of job advertisements would be incomplete without consideration of the impact of such ads on a broader audience. The paragraphs below provide insight into how and why job seekers, as well as a broader group of organizational stakeholders, react to job advertisements.

PURPOSE OF JOB ADVERTISEMENTS

Job advertisements present a powerful marketing device for organizations. Through such advertisements,

organizations can communicate multiple messages to a variety of audiences. A variety of conceptual frameworks have been used to describe job advertisements as communication mechanisms. For example, the act of placing job advertisements can be seen as an organization providing outsiders with a signal of its strength and growth. On the other hand, the placement of such ads can be seen from an impression management perspective as an attempt to communicate the values, or espoused values, that make an organization a unique business partner and employer. In this sense, organizations may place such ads with an idea of how they should be perceived by internal (e.g., employees) and external (e.g., job seekers) stakeholders. Job advertisements can also be seen as rational acts of an organization constantly balancing labor supply and demand. To this end, organizations not only place ads in papers, but also place ads in targeted professional outlets based on demand for specific knowledge and skills. Regardless of placement or intent, the primary purpose of a job advertisement is to attract job seekers to employment opportunities and motivate them to take active steps in pursuit of an available job.

The framework used to create most job advertisements either implicitly or explicitly includes four informational dimensions: organizational identity, human resource need, information needed to fill the need, and information that allows an applicant to contact the organization. Employers first must describe their organizational identity, or the values on which their business practices are based and that make them unique from other firms. Organizations can choose to describe themselves in a variety of ways but often employ more symbolic language to add a richness

to job advertisements. Job seekers reviewing such advertisements can gain insight into the defining features of an organization. Research suggests that from this language, readers extract a perception of an organization's personality. To the extent that a job seeker's personality fits with that of an organization, employment pursuit should follow.

The three other dimensions of employment ads pertain to facilitating tangible next steps in the pursuit of employment. First, the organization with a vacancy must clearly identify its human resource need (e.g., truck driver, financial analyst) and then clearly specify what is required of applicants to fill the position. Traditional job advertisements focus on tangible requirements for a job, such as years of experience or educational requirements. As organizations move toward more strategic management of their human resources, the infusion of language around required or preferred competencies associated with a job has become more popular. Such language can help promote applicant self-selection by providing an added level of insight into the type of applicant an employer seeks. Finally, job advertisements would not be complete without information that enables would-be applicants to take next steps in their employment pursuit.

As previously mentioned, the effectiveness of job advertisements as a recruitment source has been a subject of debate when measured by traditional ROI (return on investment) metrics, but not when evaluated as a broader organizational communication vehicle. Rather, employment advertisements should be seen as strategic communication vehicles targeted not only at the job-seeking public but also at competitors, employees of an organization, and the general public. Because of this, the framing of advertisements and specific content that organizations choose to include in such ads can be seen as having multiple messages. For example, a strategy of advertising that is commonly employed in job advertisements is to manipulate the perceived amount of employment opportunities available within an organization. Research in this area has shown that job seekers perceive jobs that are presented as being more scarce as having more positive attributes, such as higher salaries or better hours. At an industry level, firms that suggest they have job openings that are "going fast" signal organizational health as well as status as an employer of choice. Because job advertisements can send such signals, organizations often run

employment advertisements even though they have little hiring intent.

The subtleties of employment advertisements as communication vehicles to multiple audiences involve their physical attributes, as well. Job advertisements of healthier, more mature organizations typically contain more detailed and descriptive language reflecting an organization's position of power and tradition. In addition to the detailed language employed in a job advertisement, the prominence of an employment ad on a page has also been found to have an impact on how job seekers process information. In fact, research findings have supported the notion of a *set size effect*, which suggests that more information in job advertisements will increase readership of ads. More information in an ad, coupled with its relative size compared with others on a page, has a positive impact on its readership. Further, job advertisements that contain pictures are processed differently than purely text-based job advertisements. This phenomenon has recently become a subject of more intense inquiry as job advertisements have been deployed on the Internet, changing the nature of aesthetic flexibility afforded organizations as they promote employment opportunities.

SUMMARY AND FUTURE ISSUES

Job advertisements represent a significant source for recruiting job applicants as well as an important channel through which organizations can communicate to broader audiences. The impact of job advertisements on potential applicants can be attributed to those features that help employers frame and communicate organizational and employment information. Despite the widespread use of job advertisements, research and practical evidence suggests that such ads, in and of themselves, are not a particularly instrumental source of job applicant generation. However, because they represent such a highly visible communication channel, they should be evaluated within the context of their impact on multiple target audiences. Therefore, the future of research and applied interest in job advertisements may shift from attention to the transactional properties of job advertisements that move job seekers to become applicants toward a more strategic perspective on their function and importance.

JOB ANALYSIS

Job analysis is a label given to the process of obtaining information about jobs, which includes both the description of what is done at work and the specification of what capabilities are needed to perform the work. It is one of the most widely used organizational data collection techniques and forms the foundation on which virtually all other human resource management systems are built. Finally, its use is essential to meet legal requirements. Despite changes in the work environment, job analysis remains an essential tool for industrial and organizational psychologists.

As a process, job analysis involves a series of choices, including the type of information to collect, the method by which the data will be collected, and the source of the data. The specific choices made, however, will depend on the purpose of the job analysis (or the reason it is being conducted). Job analyses can be conducted for a number of purposes, including the following:

- Developing job descriptions that describe the essential nature of the job
- Classifying jobs into clusters or families of related jobs

- Developing selection systems, in which the job analysis is used to describe the knowledge, skills, abilities, and other characteristics needed for successful task performance
- Developing performance appraisal systems, in which the job analysis is used to identify the key tasks and work behaviors performed on the job
- Evaluating the worth of different jobs for compensation purposes
- Designing or redesigning jobs to make them more interesting or efficient to perform
- Developing training programs, in which the job analysis is used to identify the key tasks that workers must be able to perform

TYPE OF INFORMATION TO COLLECT

The type of information to collect is dictated by the purpose of the job analysis. Thus, it is essential to articulate the purpose clearly prior to starting a job analysis. With the purpose clearly defined, a variety of information can be gathered about a job. One of the most common types of information collected in a job analysis concerns work activities. *Work activities* are the observable behaviors performed by workers. There are several ways to examine work activities, varying on a continuum from very detailed actions to global behaviors. These include elements, tasks, duties, and generalized work activities. An *element* can be thought of as the smallest unit into which it is practical to divide any work activity without analyzing separate movements, motions, and mental processes. Tightening a bolt on a water pump would be an example of an element of an auto mechanic's job. There are often hundreds of elements for a job, which often makes them impractical units for most purposes. A *task* is a collection of related elements performed closely in time. Tasks have an identifiable beginning and end and are directed toward the achievement of specific job objectives. Replacing the water pump to ensure adequate engine cooling would be an example of a task from an auto mechanic's job. Most jobs can be summarized with between 30 and 100 tasks, which makes the task level very useful for numerous purposes. For example, when designing a training program, it is often helpful to have a very detailed understanding of the tasks performed on the job. This informs the content of the training program in terms of specific tasks workers need to learn.

A *duty* is a collection of related tasks that have a common focus or purpose. Rebuilding automobile engines would be an example of a duty for an auto mechanic's job. Most jobs can be summarized in terms of 6 to 12 duties. The duty level is also very useful. For example, when designing a performance appraisal system, the duties of a job can be used as the key performance dimensions on which workers are rated or judged. Finally, a *generalized work activity* is a collection of similar job activities that underlie the accomplishment of major work functions. It is similar to elements, tasks, and duties in that it focuses on what is accomplished at work, but it differs in that it focuses on higher-order behaviors. Some examples highlight the differences. Handling and moving objects, resolving conflicts and negotiating with others, and implementing ideas, programs, systems, or products are all examples of generalized work activities. Because these are more general behaviors, generalized work activities can be used across different jobs, whereas elements, tasks, and duties are typically job specific.

Another common type of information collected in job analysis is *worker requirements*, which are the underlying characteristics workers need to perform the tasks of a job. There are numerous types of worker requirements, but common requirements include knowledge, skills, abilities, and personality characteristics. *Knowledge* is defined as conceptual, factual, and procedural information that is related to task performance. Knowledge is often very specific to a job and can be divided into *declarative* knowledge (knowledge of what) and *procedural* knowledge (knowledge of how). For example, an accountant needs to have knowledge of relevant laws (declarative) as well as knowledge of how to file a tax return (procedural). *Skill* is defined as the proficiency or competency to perform a task or closely related set of tasks. Skills can be divided into *basic* skills, which facilitate learning or the acquisition of new knowledge (e.g., reading skills), and *cross-functional* skills, which are developed capabilities that facilitate job performance across job contexts (e.g., problem-solving skills). *Ability* is defined as a relatively enduring capacity for performing a range of tasks. Abilities and skills are similar, but the main distinction is that abilities are thought to be relatively enduring, whereas skills are thought to improve with experience and training. Higher-order abilities include cognitive (e.g., verbal and quantitative), psychomotor

(e.g., dexterity, reaction time), and physical (e.g., strength, hearing). *Personality characteristics* are those distinctive traits unique to an individual. It is thought that certain traits will lead to success on the job. Examples of common personality characteristics sought in workers are dependability, honesty, stress tolerance, and adaptability.

Although work activities and worker requirements are the two most commonly collected types of information in a job analysis, several other types of information can be gathered, as well. These include such things as the work context, or the broader environment within which the job is performed. For example, the work environment might be subject to extremes of temperature, noise, or danger. Another important type of information concerns licensure or certification requirements. Some jobs may require licenses or other certification prior to working on a job. For example, both lawyers (bar exam) and accountants (CPA exam) have to pass exams to work in their field. Another important type of information concerns the equipment, tools, or machines that are used on the job. Because some jobs rely heavily on certain types of equipment, tools, or machines, it would be impossible to understand them without considering these elements. Finally, *critical incidents* are often collected via job analysis. *Critical incidents* are short examples of highly effective or ineffective work behavior. They typically include a description of the situation, what the worker did, and the outcome of the worker's actions. Critical incidents are often helpful in developing anchored rating scales that can be used in the development of selection or performance appraisal tools.

JOB ANALYSIS METHODS

Once it is decided what type of information to collect, it is necessary to choose the method(s) through which to collect the data. Each method offers a slightly different perspective on the job and has different strengths and weaknesses. It is good practice to use multiple methods to collect job analysis data. There are four main methods through which job analysis data can be collected. First, the job analyst can observe the workers as they do the job. Direct observation involves recording what is done on the job, how it is done, and why the various parts of the job are performed. An advantage of direct observation is that it is

not subject to reporting biases on the part of the worker. Unfortunately, it may not be possible to observe key aspects of the job, particularly if the job involves a great deal of mental activity. For example, if one were to observe a patent examiner (who decides whether to issue a patent for a new product) as she judges the prior art (similar past products), there would be few outward manifestations of this cognitive processing.

The second method, however, overcomes this limitation of direct observation. Individual interviews involve recording workers' descriptions of what they do on the job. This format is flexible because it allows the job analyst to collect virtually any type of information. Through this method it is possible to acquire very detailed information about the job. If additional details are needed, the worker can be prompted for more information. If the worker makes statements that are questionable (e.g., an entry-level worker indicating he has very high-level responsibilities), the job analyst can directly question the validity of the statement. Drawbacks to this method are that workers may not be able to describe all that they do and it can be very time-consuming to conduct individual interviews.

The third method addresses the inherent inefficiency of individual interviews by gathering a number of workers or other subject matter experts and conducting a group interview. In addition to being more efficient, group interviews enable the job analyst to gather consensus about key job aspects. Yet there are potential problems with conformity and social loafing in group settings. Ways to overcome these problems are to structure the group interaction such that all members must contribute to the group and disagreements are actively solicited. The fourth method involves the use of surveys to collect detailed information about the job. Surveys enable the efficient collection of a wide range of types of information. For example, it is possible to collect work activity or worker requirement information on the extent to which a capability is needed at entry to the job (as well as other aspects of the capability, including level, frequency, importance, criticality, and relative time spent using). In addition, surveys enable the job analyst to quantify the work activities and worker requirements and use this information to make decisions about the job. Potential drawbacks include careless responding and nonresponses to lengthy surveys.

SOURCE OF JOB ANALYSIS INFORMATION

There are numerous sources of job analysis information, including the worker, a supervisor of the worker, a job analyst (i.e., a person trained in job analysis techniques), and archival job information (including past job analyses and databases such as the Occupational Information Network). Sources are the places where the information is collected. As with the method, each source provides a slightly different perspective on the job and has different strengths and weaknesses. When conducting a job analysis, it is important to collect information from a variety of sources to balance their strengths and weaknesses, resulting in a more accurate picture of the job. Some of the strengths and weakness of the sources are as follows. The worker (or job incumbent) typically has very high familiarity with the job (assuming adequate experience on the job) and thus should have high levels of job knowledge. Unfortunately, job incumbents are not always able to fully describe their job or otherwise articulate what it is they do in terms that are useful for job analysis purposes. In addition, workers are sometimes not motivated to provide accurate and reliable information.

Supervisors, on the other hand, are often in an excellent position to understand what worker requirements are needed for success on the job. In addition, they are less likely to be motivated to bias job analysis results. Yet supervisors may lack detailed information about the job, particularly if they have never performed it. Job analysts typically generate highly reliable ratings, have little motivation to bias the results, and are able to integrate large amounts of information and make fine distinctions among different jobs. Yet job analysts may lack adequate information about a job, particularly if there are numerous infrequently occurring tasks. In addition, because job analysts typically have prior knowledge of the job they are investigating (perhaps from a previous job analysis), they may harbor stereotypes about the job that bias their judgment. Archival job information from a source such as the Occupational Information Network is useful because it is provided at no cost to the user and it contains a great deal of comparative information on a wide range of jobs. Yet the jobs contained in archival databases may not match the jobs in the organization. In addition, the data may not be current and the specific detail

needed may be absent, requiring original data collection.

JOB ANALYSIS METHODS

A variety of job analysis methods have been developed over the years. These include work-oriented methods, which seek to describe what a worker does, worker-oriented methods, which seek to identify the characteristics needed to successfully perform job tasks, and hybrid methods, which combine elements of work- and worker-oriented methods. Because of space constraints, only methods that are widely used or prototypic are discussed here. The Further Reading section identifies other methods for the interested reader.

WORK-ORIENTED METHODS

Several work-oriented methods have been developed, including task analysis, functional job analysis, and the critical incident technique. Task analysis is perhaps the most commonly used work-oriented method for describing what a worker does.

Task Analysis

Task analysis involves a comprehensive listing of all the tasks performed in a job, such that a *task*

is defined as a collection of related elements performed closely in time. Tasks have an identifiable beginning and end and are directed toward the achievement of specific job objectives. Once all the tasks are identified, they are typically placed into a job analysis survey and rated by workers and supervisors in a variety of ways, including how frequently the task is performed, how important the task is to the job, and whether it is important to be able to perform the task as soon as one starts on the job. Because the tasks performed are typically unique to a given job, separate task analyses need to be conducted for each job.

There are at least four steps associated with conducting a task analysis. The first step involves developing a comprehensive listing of tasks. Typically, workers and their supervisors are asked to help generate lists of all the tasks that are performed on the job. This can be done through individual brainstorming, group meetings, or individual interviews. In addition, job analysts often observe the job and consult any existing documentation (e.g., training manuals, checklists, performance appraisal forms) for additional insight into the tasks. Effective task statements typically begin with an action verb that describes what the worker does, how he or she does it, and to whom or what (object) and why a worker does it.

The second step involves taking the listing of tasks and developing a job analysis survey. Similar tasks are typically grouped by duty on the survey. One key issue in this step concerns what kinds of response scales to use. It is possible to collect multiple kinds of information about the tasks. For example, it may be important to know if a worker performs the task as part of his or her job. Other potentially important information may involve how much time a worker spends on each task, how difficult the task is to perform, how frequently the task is performed, how critical or important the task is to job success, the consequences of performing the task incorrectly, and whether one needs to be able to perform the task when one starts the job (or whether it can be learned on the job). The choice of response scale(s) should be dictated by the purpose of the job analysis and the conclusions one hopes to reach. It is important to realize, however, that there is often considerable overlap between different response scales and that it is fairly easy to overload respondents with multiple, similar response scales.

The third step involves administering a job analysis survey to collect quantitative data. Choices that arise during administration include whether to use a paper-and-pencil or Web-based (or computerized)

survey and who should complete it. The choice of paper-and-pencil versus Web-based survey should be driven largely by the capability of the survey designers and the familiarity of the potential respondents with the different methods. The choice of who should complete the survey is slightly more complex. It is important to make sure that whoever completes the survey has adequate knowledge of the job in question. As such, individuals who have been working on the job for a short period of time are often excluded (or at least their data is not used when conducting analyses). It is often a good idea to collect data from both workers and supervisors because of their different perspectives on the job. It is often best to sample widely to collect as representative a sample as possible. Regardless of who completes the job analysis survey, demographic information should be collected (e.g., age, work experience, gender, education, ethnicity) so that the sample can be described and the data can be analyzed for potential differences among demographic groups.

The fourth step involves summarizing the data and developing a report. There are many ways in which task data can be summarized. Means and standard deviations are typically reported for each task. It is sometimes helpful to also report means and standard deviations for all the tasks that a particular duty comprises. In addition, it can be useful for those who are less familiar with statistics to report the percentage of respondents responding in each response category or the percentage of respondents responding above a particular predefined level (e.g., percentage of respondents who indicate a task is “important” or “very important”). In addition, depending on the application, it might be useful to report data divided by demographic group, location, or other meaningful grouping.

WORKER-ORIENTED METHODS

Several worker-oriented methods have been developed, including the Position Analysis Questionnaire (PAQ), the job element method, and the ability requirements scales. The PAQ has been the most researched and implemented worker-oriented method.

Position Analysis Questionnaire

The PAQ is a worker-oriented method that focuses on the worker behaviors that are involved in work activities. The PAQ can be used across any type of job (in contrast to task surveys). One advantage of the

PAQ is that it can be used to examine the similarities and differences among multiple jobs.

The PAQ contains 187 items assessing worker activities and work context variables (it also includes 7 items assessing pay). It has six major divisions, which include information input (where and how a worker gets needed information), mental processes (what decision-making, reasoning, and other cognitive activities are involved on the job), work output (the physical activities and tools/equipment used), relationships with other persons (the nature of interpersonal relationships required in the job), job context (the physical and social context of the job), and other job characteristics (anything else not covered in the major divisions). Within each of these major dimensions are more specific work activities, work conditions, or job characteristics.

The PAQ uses six response scales to gather data on the different items (only one scale applies to a particular item). The response scales (with their scale anchors) are as follows: (a) extent of use (nominal/very infrequent to very substantial); (b) importance to job (very minor to extreme); (c) amount of time (less than a tenth of time to almost continually); (d) possibility of occurrence (very limited to high); (e) applicability (does not apply or does apply); and (f) special scales, which are specific to a particular item.

The PAQ is best used by trained analysts because of the relatively high reading level and complexity of some aspects of the questionnaire. Typically, use of the PAQ begins with an analyst observing several workers as they perform the tasks of the job. Then the job analyst interviews workers and completes the PAQ. The analyst uses the information gathered in the interview and observed on the job to decide how to rate the job on the PAQ items. The complete forms are then scored by computer, and summary results are provided.

A large amount of research has been conducted on the PAQ since its introduction in the 1960s. Despite some criticisms, this research has generally shown the PAQ to produce reliable and valid ratings on jobs. Convergence across job analysts has been good, and the PAQ dimension scores have been shown to be related to compensation and worker ability levels.

HYBRID METHODS

Hybrid methods use elements of both work- and worker-oriented job analyses. Examples include the Occupational Information Network, the combined job

analysis method, and the Multimethod Job Design Questionnaire. The Occupational Information Network (or O*NET) is the U.S. Department of Labor's replacement for the Dictionary of Occupational Titles (DOT). As such, in many respects it represents the future of job analysis.

Occupational Information Network (O*NET)

As a result of changes in the nature of the workplace, the U.S. Department of Labor decided to replace the task-based DOT with a more modern and flexible job analysis system. The O*NET was designed with several features in mind: (a) the inclusion of multiple descriptors or content domains to capture the range of ways in which work can be described, (b) the development of cross-job descriptors to enable comparisons between different jobs, and (c) the use of a taxonomic approach to occupational classification to enable exhaustive coverage within a content domain. Using these principles, a content model was developed that identified six content domains and specific categories within each domain.

The first domain includes those *worker characteristics* that are thought to be enduring individual attributes that influence the capacities workers can develop, as well as the willingness of workers to engage in certain kinds of activities. This domain includes abilities, occupational values and interests, and work styles (or personality characteristics). The second domain includes *worker requirements*, which are general attributes that are developed through education and experience and thus are more amenable to change than worker characteristics. This domain includes knowledge, skills, and education. The third domain includes the *occupational requirements* that represent descriptors of the work itself instead of descriptors of the worker. This domain includes generalized work activities, work context, and organizational context.

The fourth domain includes those *experience requirements* that reflect the types and quantities of experience required in specific occupations, including worker experience in other jobs, job-related training, on-the-job training, and licensure or certification requirements. The fifth domain includes individual *occupation characteristics*, which reflects three aspects of the labor market: labor demand, labor supply, and other labor market information. The sixth domain includes *occupation-specific requirements*, and it

focuses on information that is unique to a particular job, including occupation-specific skills and knowledge, tasks and duties, and machines, tools, and equipment. Because this information is unique to a particular job, this domain differs from the other five domains.

The O*NET uses different response scales, depending on the domain. For example, for abilities, data is collected on the level and importance of a particular ability to the job. For work context, on the other hand, the frequency with which a particular contextual feature is present is measured. Research has shown relatively strong relationships between different response scales for the same descriptor, suggesting redundancy in the scales. In contrast to the analyst-derived ratings of the Dictionary of Occupational Titles (DOT), O*NET relies on the judgments of the workers themselves. Because the O*NET is new, there is less information on the reliability and validity of the various domain descriptors, although initial results suggest the ratings are reliable.

The O*NET differs from previous job analysis methods in several ways. First, it focuses on occupations as opposed to jobs. In some instances occupations are the same as jobs, and in other instances multiple jobs would be combined under a single occupational title. For example, the DOT summarized information on more than 12,000 jobs; the O*NET includes roughly 1,000 occupations. Although some of the 12,000 job titles in the DOT are either redundant or obsolete, it is not clear that the dramatic reduction in occupational titles will meet all the needs of potential users of O*NET. Second, it combines a wider range of data that resides at many levels of analysis. For example, O*NET collects information on the economic, organizational, job, and individual levels. One of the challenges of this wide array of data, however, is that it is not clear that all of these levels make sense at the occupational level. Third, the O*NET is an Internet-based system that is accessible by any potential user. In fact, there is a Web site (<http://www.onetcenter.org/>) where one can access the O*NET surveys or database. It is even possible to download the latest version of the database and perform additional analyses. Thus, O*NET represents an excellent starting point when conducting a job analysis study.

JOB CHARACTERISTICS THEORY

The primary objectives of job characteristics theory (JCT) are to explain how properties of the organizational tasks people perform affect their work attitudes and behavior, and to identify the conditions under which these effects are likely to be strongest. The most recent version of the theory is shown in Figure 1. As shown in the figure, the theory posits that five core characteristics of the work itself affect a variety of personal and work outcomes via their effects on three psychological states of employees. In addition, the theory argues that these core characteristics have their strongest effects when employees score high on three

individual conditions: growth need strength, context satisfaction, and knowledge and skill.

The conceptual core of the theory is the set of three psychological states that mediate between job attributes and outcomes. They are as follows:

- *Experienced meaningfulness*. The degree to which the jobholder experiences the work as inherently meaningful, as something that counts in his or her own system of values.
- *Experienced responsibility*. The degree to which the jobholder feels personally accountable and responsible for the results of the work he or she does.
- *Knowledge of results*. The degree to which the jobholder has confident knowledge about how well he or she is performing.

Job characteristics theory posits that the simultaneous presence of these three psychological states results in a number of favorable personal and work outcomes. Specifically, the jobholder should (a) be internally motivated at work (i.e., feel good when performing well, and feel bad or unhappy when performing poorly), (b) be satisfied both with the opportunities for personal growth and development at work and with the job in general, and (c) perform effectively at work (i.e., produce work that is high in both quantity and quality). However, if one or more of the psychological states is absent or at very low level, fewer of these desirable outcomes should emerge.

The three psychological states are internal to individuals and therefore do not represent properties of the work itself that might be changed or redesigned. Job characteristics theory identifies five characteristics of jobs that, when present at high levels, increase the chances that a jobholder will experience the three psychological states and, through them, shape the personal and work outcomes. The specific job characteristics that are expected to most strongly influence each of the psychological states are (a) skill variety, (b) task identity, (c) task significance, (d) autonomy, and (e) feedback. These characteristics are described in the following paragraphs.

Experienced meaningfulness is shaped by three job characteristics: skill variety, task identity, and task significance. *Skill variety* is the degree to which carrying out the work of the job requires a number of activities, which involve the use of a number of skills and talents of the jobholder. Work that stretches one's skills and abilities invariably is experienced as more meaningful than work that is simple and routine. *Task Identity* is the

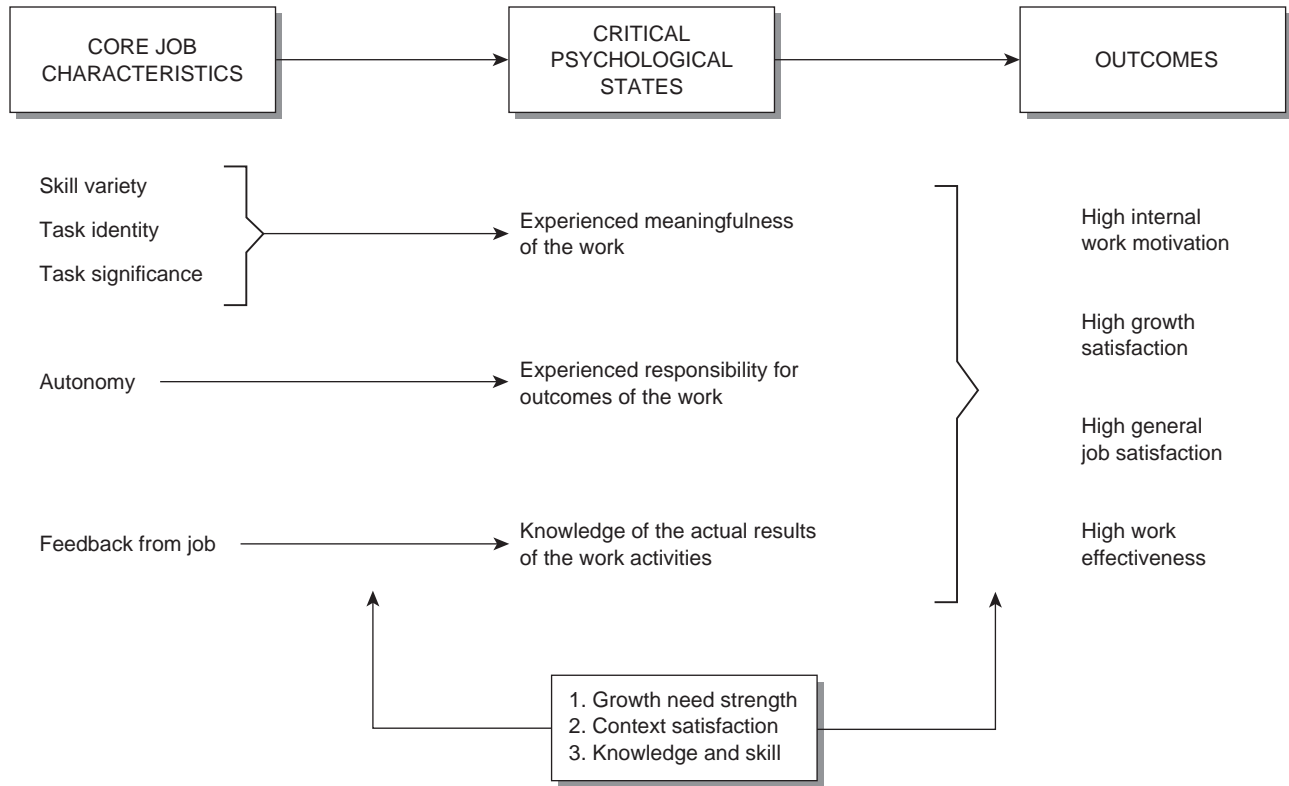

Figure 1 Job Characteristics Theory

degree to which the job requires completion of a whole and identifiable piece of work—doing a job from beginning to end with a visible outcome. Putting together an entire product or providing a complete unit of service is inherently more meaningful than being responsible for only a small part of the work. *Task significance* is the degree to which the work has a substantial impact on the lives of other people, whether in the immediate organization or in the external environment. An activity that is consequential for the psychological or physical well-being of others is typically experienced as more meaningful than is work that makes little difference to anyone else. These three job characteristics are expected to be additive, in that meaningfulness is enhanced to the extent that any or all of them are present.

Experienced responsibility is shaped by the amount of autonomy the job provides. *Autonomy* is the degree to which the work is structured to provide the employee with substantial freedom, independence, and discretion in scheduling the work and in determining the

procedures to be used in carrying it out. For high-autonomy jobs, the outcomes of the work depend on the jobholder’s own efforts, initiatives, and decisions, rather than on the instructions of a manager or a manual of job procedures. In such circumstances, the jobholder feels greater personal responsibility for his or her own successes and failures at work.

Knowledge of results is shaped by *feedback* from the job—that is, the degree to which carrying out job-specified work activities provides the jobholder with direct and clear information about the effectiveness of his or her performance. When someone receives information about his or her performance from the work itself (e.g., when a salesperson closes a deal and receives payment from a customer), that feedback is direct and immediate and therefore contributes substantially to his or her overall knowledge of results about work outcomes.

The degree to which a job has an overall high standing on the five characteristics described here, and therefore is likely to prompt favorable personal

and work outcomes, is summarized by an index called the Motivating Potential Score (MPS). To engender all three of the psychological states, a job must have a high standing on one or more of the three characteristics that boost meaningfulness and be high on both autonomy and feedback, as well. The MPS score indicates the degree to which that is the case through the following formula:

$$\text{MPS} = (\text{skill variety} + \text{task identity} + \text{task significance})/3 \times \text{autonomy} \times \text{feedback}$$

Thus, a low score on either autonomy or feedback will substantially reduce a job's MPS, because both experienced responsibility and knowledge of results must be present for personal and work outcomes to be high, and those two job characteristics produce the corresponding two psychological states. Conversely, a low score on one of the three job characteristics expected to foster experienced meaningfulness may not necessarily compromise a job's MPS, because the absence of any one of those three attributes can be compensated for by the strong presence of the others.

As shown in Figure 1, the theory identifies three individual conditions (i.e., growth need strength, context satisfaction, and knowledge and skill) as moderators of the impact of the core job characteristics on an employee's responses. Jobholders are expected to respond most positively to jobs high in motivating potential when they score high on all three of these individual conditions.

Growth need strength (GNS) is the strength of an individual's need for personal accomplishment, learning, and development at work. The theory posits that jobholders who have strong growth needs value the opportunities for accomplishment and self-direction provided by jobs high on the five core characteristics and, as a result, respond positively to them. Low-GNS jobholders, by contrast, place less value on the opportunities provided by high-MPS jobs and therefore respond less positively to them.

Context satisfaction refers to the extent to which employees are well satisfied with major elements of the work context (e.g., pay, job security, coworkers, and managers). When individuals are satisfied with the context of their work, they are likely to focus their attention on the properties of a job high in motivating potential. As a result, they should appreciate and respond positively to those properties. However, dissatisfaction with the context may distract employees'

attention from the core job characteristics and orient their energy instead toward coping with the experienced problems.

Knowledge and skill refers to the extent to which the employee has the skills and competencies necessary to complete a job high on the five core characteristics. When individuals have such skills, they have the potential to successfully complete jobs high in motivating potential and, therefore, to reap the personal and psychological rewards provided by those jobs. By contrast, when employees are missing these skills and competencies, they are likely to experience a good deal of frustration and unhappiness on jobs high in motivating potential, precisely because these jobs offer psychological rewards for effective performance, but the employees are unable to perform well enough to obtain these rewards.

Many of the empirical tests of JCT have used the Job Diagnostic Survey (JDS), a research instrument that was developed to assess many of the constructs specified by the theory. Specifically, the JDS assesses jobholders' perceptions of the five core job characteristics, their experienced psychological states, their GNS, and affective outcomes including internal motivation, growth and job satisfaction, and satisfaction with several aspects of the work context. The JDS does not assess jobholder work effectiveness or knowledge and skill.

RESULTS OF RESEARCH

More than 200 studies have used the JDS to test all or portions of JCT, and the results of these studies provide some support for many of the major tenets of the theory. In particular, results suggest that the higher the job is on each of the five core job characteristics, the higher the jobholder's growth and job satisfaction, internal motivation, and work effectiveness. Also, results from numerous organizational change projects suggest that when jobs are boosted on the five core characteristics, improvements in jobholder satisfaction and work effectiveness result. For example, these studies show that changing the jobs so that employees receive more direct feedback from the work itself and have more personal freedom and independence at work typically results in higher levels of work effectiveness and job satisfaction.

Research also shows that the core job characteristics affect the personal and work outcomes via their effects on the three psychological states specified by

the model. That is, the presence of the five job characteristics increases the experience of the three psychological states, which then positively influence the jobholder's satisfaction, internal work motivation, and work effectiveness. Finally, there is some evidence that individuals respond most positively to jobs high on the core characteristics when they have high GNS. Specifically, employees who work on jobs high in motivating potential tend to be more effective and internally motivated when they have strong needs for personal accomplishment and development.

Although research supports many of the basic tenets of JCT, other parts of the theory have received relatively little research support. One of these involves the summary index of the overall motivating potential of jobs, MPS. Previous studies suggested that the MPS index is *not* more predictive of outcomes than a simpler index computed by merely adding up scores on the five core job characteristics that have been derived from the JDS. Although the MPS index does make conceptual sense, it is likely that these weak results are a function of the psychometric properties of the JDS, which do not allow for the multiplication of variables specified in the formula for the MPS score.

Another element of JCT that has received little support involves the proposed moderating effect of context satisfaction. Although some studies show that individuals respond more positively to jobs high in motivating potential when they are satisfied with the context, others indicate that satisfaction with the context has little to do with their reactions to the core job characteristics. Given these results, the role of context satisfaction in JCT remains unclear. Finally, no previous studies have examined the effects of jobholders' knowledge and skill on their reactions to the core characteristics, and therefore it is not yet clear if individuals respond more positively to the job characteristics when they have high levels of knowledge and skill.

More research is now needed that investigates the effects of an individual's skills and context satisfaction on the relation between the job characteristics and the personal and work outcomes. Because JCT posits that employees respond most positively to the core job characteristics when GNS, context satisfaction, and knowledge and skill are *all* present at high levels, a reasonable start might be to directly test this argument by including in a study measures of all of these conditions in addition to measures of the job characteristics and the personal and work outcomes. Results of

such a study could provide important information about the conditions that should be present if jobs high in motivating potential are to have positive effects on employees' personal and work outcomes.

JOB CHOICE

The topic of job choice subsumes all the activities involved in the process of deciding where to work. The concept underlying job choice research is that individuals are motivated to find work consistent with their preferences and goals. Job seekers engage in a goal-directed search process and compare each potential job relative to alternatives. The job choice literature has been heavily informed by the literature on recruiting and person–environment fit. The unique contribution of research on job choice is the focus on

the individual job seeker and his or her information acquisition and decision-making strategy.

EXPECTANCY AND JOB CHOICE

Most job-choice models start from some variant of expectancy theory. Job seekers begin from a set of alternative jobs and then evaluate the attractiveness of each alternative based on key attributes. Examples of relevant attributes include instrumental attributes such as compensation and working conditions, affective or interpersonal attributes such as relationships with coworkers, and cognitive attributes such as intrinsic interest in job tasks and achievement on the job. Each job's attractiveness is based on valence, instrumentality, and expectancy:

- *Valence*: the personal importance weights (e.g., valences) each job seeker attaches to each attribute that a job might possess. Job seekers vary in the emphasis they put on each attribute, so some job seekers will be most interested in getting a well-paying job, whereas others will be comparatively more interested in a job with a good social environment, and others will be more interested in work that provides a sense of accomplishment.
- *Instrumentality*: the probability of acquiring each of the attributes for each job. Attributes are represented as probabilities, because although job seekers have beliefs about the likely attributes of each job, these attributes are not known with certainty. A job seeker who actually knows someone who works at a company will have more confidence in his or her estimates of the job's attributes than a job seeker who knows about a company only through a recruiter. The job seeker with the inside connection will therefore place a higher instrumentality on the job attributes than will the job seeker who has only recruiter information.
- *Expectancy*: job seekers' evaluations of their ability to obtain a job and perform well if hired. Self-efficacy or self-esteem increase the expectancy related to each job's positive attributes, whereas the perceived difficulty of obtaining a job during the selection phase and difficulty performing well once on the job decrease expectancy.

The final decision process is represented by the underlying triple product term of expectancy \times instrumentality \times valence. The higher the value of this product term, the more likely it is that a job seeker will pursue a given job.

The expectancy model of job choice has fared well as a predictive device, although its accuracy is far from perfect. Expectancy's strictly rational perspective on job choice and individual outcomes is misleading if taken in isolation, given research demonstrating the importance of heuristics, moods, and emotions in decision making. Prospect theory suggests that individuals are risk averse when it comes to positive events and risk seeking when it comes to negative events. For example, prospect theory suggests that decision makers will prefer a job with high probability of a few positive elements and a low chance of several negative elements relative to a job with low probability of several positive elements and a high chance of a few negative elements, even if a strictly linear model such as expectancy would anticipate that the jobs are otherwise equivalent. Moreover, other decision-making research suggests that the weighting of job attributes is not a mathematical combination of all relevant attributes but rather is a more affect-driven process centered on a small number of salient attributes.

Expectancy models raise a number of informative questions about job attributes and individual valences but do not provide a system for understanding the processes underlying the assessment of jobs. Factors such as the intensity of job search, contextual limitations on job choice activities, and even the social connections at work must be addressed from other theoretical perspectives. In addition, expectancy theory formulations leave unanswered questions about how job seekers develop beliefs about the attributes of each job option. By adding behavioral decision making and process-oriented versions of job search to the expectancy formulation, a more complex picture of choice is emerging that uses the decision maker's active participation in the process as a central theme.

DEVELOPING A CHOICE SET

Job seekers actively attempt to improve their match with their work environment during the job search process. Theoretically, those with more information will be better able to assess the extent to which they will match with their new positions. Therefore, the process of searching for a job is a major component of the job choice literature.

A job search process is initiated when an individual determines that his or her current employment situation is not meeting key employment goals. Thus, the

first choice that an individual makes in the job choice process is that a new job is needed. Meta-analytic research has demonstrated that individuals with higher financial need and employment commitment engage in more intense job search, which is consistent with the concept that these individuals place greater valence on a new job relative to those with less financial need or lower employment commitment. Evidence shows that those higher in self-esteem and self-efficacy engage in more active job search behavior, which is consistent with the concept that such individuals have greater expectancy of finding and obtaining a new job than do those with less self-confidence.

Job seekers use several techniques to find information regarding jobs and create their estimates of job attributes and the associated probabilities of obtaining each attribute. Evidence suggests that for most individuals, a social network is critical to the process of job search. Many of these networks are informal, including word of mouth provided by family and friends. Such sources are deemed more trustworthy in persuasion research and therefore produce descriptions of job features that have higher instrumentality. An important secondary source of information used by job seekers is formal organizational announcements regarding open positions. Because the organization is believed to have a vested interest in increasing application activity, job seekers attach lower instrumentality to these promised rewards. Job seekers also make inferences regarding culture based on the image an organization projects through product advertising and media coverage in professional magazines. Some organizations, cognizant of the importance of image, have begun to carefully craft an employment "brand" for themselves using techniques from marketing. Many of these techniques are designed to supplement rational information regarding options with appealing emotional images regarding alternatives.

VALENCE OF OUTCOMES: JOB ATTRIBUTES

Once individuals are aware of potential jobs, the question of how they evaluate job attributes arises. Attraction to an organization is at least partially determined by the set of recruiting activities described elsewhere in this encyclopedia. But attraction is also shaped by factors that are more directly related to the rewards that come with a job, characteristics offered by the work, and organizational reputation. Certainly, some job preferences differ from person to person, but

research also suggests that some job characteristics have high valence for nearly all job seekers.

Research in the area of labor economics suggests, not surprisingly, that most voluntary turnover involves a change from a lower paying job to a higher paying job, which demonstrates that most individuals do place a high valence on monetary compensation. Simulation studies, in which respondents indicate which of several potential alternative positions is most attractive, support the central importance of compensation in job choice, as well. Among managerial employees, the perceptions that a job offers opportunity for advancement, challenging or interesting work, positive organizational climate, and benefits are also rated as highly valenced features. Advancement usually entails higher compensation, further underscoring the importance of monetary rewards in the job choice process. Advancement also provides the promise of achievement and interesting new work tasks. There is less information regarding the specific job characteristics preferred by other populations, including professionals, service workers, and blue-collar workers.

Another factor that might influence an individual's decision to apply for or accept a job offer is the reputation of the employing organization. The publication of guides to the best companies to work for in America and the like suggest that there is a keen interest in the corporate culture from potential employees. Such guides often describe the social aspects of work and suggest that valence is attached to more than just money. In terms of employment reputation, a perception of corporate concern for employee well-being is associated with job choice intentions among potential applicants. One related possibility is that firms can attract applicants with a progressive stance on certain social issues. Although there is limited evidence on this issue, there is some data to suggest that applicants do take elements of an organization's social responsibility into account.

DIFFERENT VALENCES: PERSONALITY AND JOB PREFERENCES

One major implication of studying the active decision maker is that individual differences should be considered. Whereas expectancy theory suggests individuals have different valences, matching models take this proposition a step further and investigate *why* different job seekers prefer different jobs. Matching models propose that individuals bring certain productive

characteristics or “supplies,” including their skills and abilities, as well as their preferences or “demands” for work environments with them into a new job. Organizations similarly have work environments or “supplies” to provide to workers, as well as job requirements or “demands” for employees. A match occurs when the supplies of workers match the demands of organizations and the demands of workers match the supplies of organizations.

The dominant paradigm in the literature on personality and job preferences comes from the program of research on the realistic–investigative–artistic–social–enterprising–conventional (RIASEC) circumplex. The basic propositions of the RIASEC model are that there are stable differences in preferences and abilities related to work characteristics, and that individuals who are in jobs that match their preferences will be more satisfied. Job preferences using the RIASEC model are measured by having individuals read descriptions of major job tasks from a variety of occupations and indicate which sound appealing to them and which they can do well. Each individual is given a profile consisting of his or her most suitable occupational types. Basic definitions for tasks found under each of the six types are as follows:

- *Realistic*: engaging in physical activities, including working with machines, objects, or related tools
- *Investigative*: solving problems, gathering information, analyzing data, and other scientific or research-related activities
- *Artistic*: creating new ideas, using creativity, and producing innovative solutions
- *Social*: working closely with others in providing information, collaborating, or directly providing assistance to customers, clients, or patients
- *Enterprising*: persuading others, leading groups, and managing organizational resources
- *Conventional*: completing detail-oriented tasks with a clear system for evaluating outcomes, or with directions provided by others

Jobs call on varying levels of each of these activities. For example, work as an industrial/organizational psychologist is highest on the investigative dimension, whereas work as a business executive is highest on the enterprising dimension. The RIASEC inventories are used frequently by vocational counselors as a tool to aid job seekers.

The RIASEC types are stable over time and are related to other measures of personality. Individuals

high in artistic and investigative interests tend to also be high in openness to experience. Individuals high in enterprising and social interests tend to be more extroverted. The relationships of conscientiousness, agreeableness, and emotional stability with any of the RIASEC dimensions are more tenuous. Despite partial overlap with personality, RIASEC dimensions are superior predictors of job choice. For example, although RIASEC dimensions rated at graduation from school were consistently predictive of employment in commensurate jobs in one study (e.g., realistic individuals tend to hold jobs higher in realism), other elements of the five-factor model explained almost no variance in job choices after RIASEC scores were taken into account.

Although the RIASEC model has investigated fit between job seekers and work characteristics, other research has investigated the fit between job seekers and organizational culture. Much of the research on organizational culture and fit has been assessed through the use of a forced-distribution preference inventory called the Organizational Culture Profile (OCP). Job seekers are asked to rank potential organizational attributes on a list from most preferred to least preferred, and then individuals familiar with the organization sort these same attributes from most descriptive of the organization’s culture to least descriptive of the organization’s culture. A match occurs when the job seeker’s desired culture is commensurate with the organization’s extant culture. Research across several studies has shown that even after statistically controlling for attractiveness of job attributes, a match between individual preferences and organizational culture predicts job choice intentions.

PUTTING IT ALL TOGETHER: DECISION PROCESS STUDIES

There are comparatively few studies that currently address the process by which individuals make job choice decisions, but the research that does exist provides some insights into the manner in which individuals evaluate evidence for each job. Consistent with the literature on persuasion and decision making, the emphasis here is on how individual job seekers come to believe that jobs have certain attributes and on how they evaluate the relevance of sources of information differently.

Research on decision-making processes under the rubric of image theory has suggested that it is not

cognitively efficient to consider all possible alternatives. Instead, decision makers are likely to engage in a multiple-stage evaluation of options. The first stage is a screening process, wherein decision makers quickly scan through the critical features of alternatives and eliminate those that fail to meet certain minimum standards. After screening out options, the second stage is selecting the most attractive options from those that remain. The selection process is much more deliberative and entails many of the elements of a more classic expectancy formulation. Another important component of image theory is that decision makers do not consider their options most of the time, but act out of habit by following cognitive scripts. This means that many individuals do not make routine choices about all available jobs, but consider jobs based on only their most familiar options.

One conclusion that can be reached is that individuals place a heavy weight on negative information in the recruiting process. In general, signs of trouble or difficulty regarding a potential job have a stronger impact on job-seeker attitudes toward an organization than does positive information about a job. The tendency for job seekers to prefer a job presented primarily in positive terms to a job presented in partially negative terms is a potential avenue for investigation of mood in job choice, although there is not a great deal of evidence on this proposition. The differential weighting of negative and positive job elements, and aversion to taking an option with negative characteristics, is consistent with prospect theory.

Another important component of the job choice process is the development of inferences regarding an organization's policies and practices from distal sources of information. It has been noted previously that many individuals draw inferences regarding an organization's policies and practices from discussions with family and friends. Without these interpersonal contacts, applicants try to draw inferences from their interactions with individuals they encounter during the recruiting and hiring process. Many of the key findings are consistent with the literature on persuasion. Applicants generally make more positive inferences about an organization when the messages are delivered by a sympathetic or attractive recruiter who provides a positive message in an informal tone. Other studies have shown that interviewers who make use of marketing and sales skills are more effective.

Decision process studies do suggest that recruiter characteristics influence inferences about the

organization, but almost all studies suggest that job attributes have a much stronger influence on the likelihood of job acceptance than do recruiting activities. Results typically show that recruitment activities are significantly related to reactions only at the initial interview stage. Job attributes, on the other hand, are significant predictors of reactions in all subsequent stages. These results suggest that the importance of the job choice is too great for employees to make decisions simply on the basis of the person conducting an interview unless the interviewer's characteristics are translated into a perception of the job's characteristics. This tendency to use a rational approach for important decisions when feasible is consistent with the literature on persuasion. However, it is also possible that the affective tone generated by organizational efforts influences job choices in ways that have not yet been investigated.

SUMMARY

Research on job choice provides a unique window on how individuals come to select a specific organization as their place of work. The key processes underlying job choice research include a search for job alternatives, evaluation of job attributes, and then a final selection process. Further knowledge of the process of job choice will be of use for individuals trying to select their ideal job as well as for organizations trying to design messages that will appeal to an appropriate audience of job seekers.

JOB CONTROL

See EMPOWERMENT

JOB DESCRIPTION

A *job description* is a written summary of what is done on a job, how the work is accomplished, and why the work is performed. The purpose of a job description is to convey the essential features of a job to a person not familiar with the job in question. Job descriptions are the most common output of a job analysis and are used for a variety of purposes, including recruitment and selection, training and development, performance appraisal, compensation, and job design.

Distinctions have been made between a job description and a position description. A *position description* summarizes what one person in an organization does, whereas a job description summarizes a number of related positions. A position description is typically used when an individual performs a relatively unique

set of activities, and a job description is used when there is enough commonality across positions to justify treating multiple positions as a single job.

There is great variability in the structure and length of job descriptions. The job descriptions provided in the *Dictionary of Occupational Titles* (DOT) are each a single paragraph in length and primarily describe the key tasks performed in the job. Other job descriptions vary from one to three pages and contain considerably more information. There are three essential parts to a job description. First, there should be some information that uniquely identifies the job. At a minimum, this would include a job title but can also include identifying details such as the department, location of the job, job code, pay range, grade level, and reporting relationships. Second, there should be a job summary that conveys the essential features of the job and what a worker does. Included in the job summary would be the purpose of the job. Enough information should be provided in the job summary to enable it to be differentiated from other jobs.

Third, there should be a listing of essential duties or work activities of the job. This listing would cover the what, how, and why of the job. Describing what a worker does involves considering the physical and mental activities that are performed on the job. Physical activities include actions that involve observable physical effort. For example, workers might assemble, inspect, or remove parts in the manufacture of an automobile engine. Mental activities include actions that involve unobservable mental effort. For example, workers might judge, evaluate, plan, or compare the performance of a key supplier of raw materials to the organization. Describing how work is accomplished involves considering the methods or procedures used to perform key job duties. These can include tools, equipment, routines, checklists, or other work aids. Describing why a worker performs these specific activities reflects the overriding purpose or reasons the duties are performed. In other words, it is important to articulate the purpose of specific duties (given the overall purpose of the job) in the job description.

Finally, some job descriptions contain additional information depending on the particular application. This might include identification of key responsibilities (useful for job evaluation purposes), a listing of accountabilities (the major results for which the work is accountable), a description of the working conditions (e.g., temperature, noise), and the nature of social relationships at work. Last, some job descriptions

identify the major knowledge, skills, abilities, and other characteristics (KSAOs) needed to perform the major work activities. The summarization KSAOs needed in a job have been referred to as a *job specification* and are often viewed as distinct enough to be treated separately from the job description because they serve to identify what individual differences are needed to perform the major work activities of the job.

JOB DESIGN

Job design has generated substantial theoretical and empirical interest in the past decades. The purpose of this entry is to describe and evaluate the most significant approaches to job design.

DESIGNING JOBS FOR INDIVIDUALS

Industrial Engineering

The first to undertake job design for individuals was Frederick W. Taylor, who developed the industrial engineering or *scientific management* approach in 1911. Taylor's approach dictated four specifications. First, work should be studied scientifically to identify the most efficient method for accomplishing tasks and allocating them among employees. Second, employee–job fit should be optimized, so that employees should be mentally and physically capable of performing their jobs but not be overqualified. Third, employee training should be based on the scientific analysis of the work and regularly monitored to ensure optimum performance. Finally, employees should be motivated with monetary bonuses.

Advocates of the industrial engineering approach suggested that it would produce several positive outcomes for organizations, including an increased pool of job applicants capable of performing highly specialized and simplified jobs and the centralization of resources. The wage-lowering effect of this large job applicant pool would in turn reduce training costs, and resource centrality would increase the overall efficiency and productivity within the organization. As a result, by the 1950s, most manufacturing jobs were designed according to the industrial engineering approach. Additional research, however, revealed that the approach led to a number of unintended negative consequences. These consequences included dissatisfaction with routine and standardized tasks, increased tardiness, reduced motivation and productivity, and sabotage of work equipment. Thus, the gains of the industrial engineering approach were often more than offset by its negative effects. The problems associated with the industrial engineering approach led to the development of alternative approaches to job design. These new approaches focused on designing work for high productivity without the psychological costs to the employee. We discuss several of these approaches below.

Motivator-Hygiene Theory

The motivator-hygiene theory (MHT), which was developed by Frederick Herzberg and his colleagues in the 1960s, represents a significant deviation from the industrial engineering approach. Central to the theory is the distinction between motivator and hygiene factors. *Motivator factors* are intrinsic to the work itself and include responsibility, achievement, recognition, and personal growth in competence. *Hygiene factors* are associated with the job context or work setting and include relationships with peers and subordinates, quality of supervision, base wage or salary, benefits, and job security. According to MHT, motivator factors increase workers' motivation and satisfaction on the job, and hygiene factors merely prevent job dissatisfaction. High employee motivation and performance can thus be achieved by enriching jobs so that they have high levels of motivator factors. A central component of job enrichment is *vertical loading*, which adds planning and evaluation duties to jobs to increase responsibility, complexity, and personal growth. Herzberg's theory has inspired a plethora of research and several successful change projects that support the contribution of motivator

factors to individual and organizational outcomes. His procedure for implementing job enrichment has also successfully guided many job redesign projects.

Nevertheless, MHT has several weaknesses. First, research has not always supported a clear distinction between motivator and hygiene factors. In particular, some job outcomes, such as pay raises, appear capable of serving as both hygiene and motivator factors. Second, the degree to which motivator factors are present in jobs is difficult to assess, given the lack of a suitable measurement technique or instrument for doing so. Finally, the theory fails to consider the impact of individual or cultural differences on motivator and hygiene factors.

Job Characteristics Model

The job characteristics model was developed by J. R. Hackman and G. R. Oldham in the 1980s as an attempt to overcome the shortcomings of MHT. Specifically, Hackman and Oldham proposed that five core job characteristics (skill variety, task identity, task significance, autonomy, and job feedback, each of which is defined below) affect three critical psychological states: experienced meaningfulness of work, experienced responsibility for work outcomes, and knowledge of work results. These three psychological states, in turn, positively contribute to personal and work outcomes, namely high intrinsic work motivation, job performance, job satisfaction, and reduced absenteeism and turnover. Finally, individual difference variables, including *growth need strength* (GNS; the desire for learning and personal accomplishment at work), knowledge and skills, and context satisfaction (satisfaction with supervisors, coworkers, income, and job security), moderate the relationships among job characteristics, psychological states, and personal/work outcomes.

The first of the five core job characteristics, *skill variety*, refers to the number of different skills needed to accomplish a job. *Task identity* focuses on whether the job requires completion of a whole, identifiable piece of work. *Task significance* refers to the job's impact on the lives of other people in the organization or on society at large. *Autonomy* refers to the employee's level of freedom, independence, and discretion in determining how and when to do his or her job. Finally, *job feedback* refers to the degree to which work activities provide the employee with direct and clear information about his or her job performance.

According to the model, employees will respond positively to job characteristics when they have high GNS, the requisite knowledge and skills, and high satisfaction with job context factors. To measure the model's variables and assess the model's validity, Hackman and Oldham developed the Job Diagnostic Survey (JDS). The results of more than 200 studies conducted on the model have generally supported the model's major premises. In particular, there is strong evidence for the expected relationships between job characteristics and employee affective reactions (job satisfaction, growth satisfaction, and internal motivation). There is also support for the associations between job characteristics and behavioral outcomes (performance and absenteeism), although the magnitude of these associations is weak. Last, research has generally supported the mediating role of the psychological states, although questions about the precise relationships between the job characteristics and the psychological states remain.

Future Prospects for the Job Characteristics Model

Increased globalization and the emergence of complex service- and knowledge-based sectors have led scholars and researchers to suggest modifications and extensions of the job characteristics model to improve its validity and usefulness. One shortcoming of the model is its focus on relatively few job characteristics. Other researchers have suggested an expanded model that includes (for example) a job dimension concerning opportunities for acquisition of new skills in an increasingly complex, diverse, changing, and uncertain work environment. The growing complexity of the work environment also suggests the need to include additional contingencies (moderators) in the model. Such contingencies can be classified into three levels: individual (e.g., interpersonal trust), group (e.g., norms), and organizational (e.g., interdependence, uncertainty). The physical environment may also serve as a contingency. Some studies have found that the effect of a job's design on individuals' responses is contingent on the spatial characteristics of the work unit, such as distance between workstations, number of workstation boundaries, density, and openness. Further research has also shown that chronic noise among industrial employees, even at a moderate level, tends to weaken or even reverse the effects of enriched (complex) jobs on affective (job

satisfaction), behavioral (absenteeism), and health-related (blood pressure) outcomes.

Two additional contingencies are time and culture. Like other motivation theories, the job characteristics model is largely nondynamic and fails to incorporate the construct of time into its premises. For example, jobs with low levels of job characteristics may still elicit high motivation and performance, if the jobholders view such jobs as temporary but necessary stepping-stones to future enriched jobs. Additionally, job characteristics and individual differences may not be independent of each other. For example, individuals with high GNS are more likely to attempt and succeed in further enriching their jobs. Thus, over time, jobs become better matched to the preferences of the jobholders.

Finally, globalization of the work environment necessitates the study and understanding of how different cultural backgrounds affect job characteristics. Thus we must take into account the importance of culture accommodation in job designs. For example, research has shown that empowerment (high autonomy) in India was associated with lower job satisfaction because of the lack of fit between the concept of empowerment and a culture that emphasizes hierarchy and status.

An Interdisciplinary Framework

A recent development in the job design area is the *interdisciplinary viewpoint*. This approach classifies previous job design approaches into four types—motivational, mechanistic, biological, and perceptual/motor—and argues that changes associated with each will result in different work outcomes. The motivational approach focuses on increasing the motivational aspects of jobs to enhance employees' motivation, satisfaction, and effectiveness. Next, the mechanistic approach focuses on human resource efficiency as the major component of efficient outcomes, such as improved staffing and low training costs. The third type, the biological approach, focuses on optimizing the physical environment to minimize employees' physical efforts, fatigue, aches, pains, and health complaints. Last, the physiological/motor approach aims to ensure that the job requirements or the physical characteristics of equipment in the workplace do not exceed people's cognitive capabilities, such as attention and concentration. In short, the approach

aims to reduce mental overload, fatigue, stress, and boredom, which in turn should reduce errors and accidents.

The interdisciplinary viewpoint considers both the benefits and costs of each job design approach. For example, the motivational approach focuses on higher job complexity, which increases employees' motivation and performance, but with the expense of increased staffing difficulty, higher training requirements and cost, higher error rates, and higher stress and mental overload. In contrast, the mechanistic approach focuses on reduced training time and lower likelihood of error, overload, and stress, but with the expense of lower job satisfaction and motivation. The biological approach focuses on reduced physical effort and fatigue, fewer health complaints, and higher job satisfaction, with the expense of higher financial costs associated with changes in equipment or the job environment. Finally, the perceptual/motor approach focuses on higher utilization levels and lower likelihood of errors, accidents, training time, and overload and stress, with the expense of lower job satisfaction and motivation.

According to this theoretical perspective, job design should optimize the cost/benefit tradeoffs of each design approach. The Multiple Job Design Questionnaire (MJDQ) was developed to assess employees' perceptions of the job elements related to each approach. Studies based on the MJDQ have provided some support for the interdisciplinary viewpoint, in that they confirm the predicted relationships between the approaches' job elements and the particular outcomes associated with those approaches. However, although the interdisciplinary viewpoint is both comprehensive and integrative, there is a need to better incorporate the four approaches into a theoretically coherent framework, as well as to take into account individual differences in reaction to the different design approaches.

DESIGNING JOBS FOR TEAMS

Quite often, the complexity of the work and the technology used require employees to work in teams. In principle, the job dimensions relevant to the design of individual jobs are also relevant to the design of team jobs. The interdependence among team members suggests that to understand the effect of job characteristics at the team level, it is necessary to

take into account a number of contingencies, such as level of cohesion, team composition, trust, group norms, task interdependence, and shared knowledge. For example, research has shown that self-managed teams with high levels of individual autonomy performed better when trust level was low rather than high, because the low trust led to increased monitoring within the team, which enhanced team performance. Others have found that the positive relation between team control over planning and work processes and team job motivation decreased as team interdependence increased. Future research should continue to systematically examine the contribution of job characteristics to teams' psychological and behavioral outcomes.

JOB EVALUATION

Job evaluation may be defined as a systematic, objective process of determining the worth of jobs to an organization. It is important to note that a job evaluation evaluates jobs (e.g., marketing manager, financial analyst) and not the people in those jobs (e.g., Mary Smith; David Johnson). Organizations use the results of this process to help determine the appropriate salaries or wages for different jobs. Job evaluation has also frequently been used to conduct comparable worth studies. Most medium and large organizations use some form of job evaluation in determining salaries and wages for their employees.

JOB EVALUATION METHODS

The numerous methods for conducting a job evaluation range from relatively simple approaches (e.g., ranking) to more sophisticated, complex approaches (e.g., point-factor). Job evaluation methods also differ in terms of whether they are standardized systems or whether they are custom-tailored to the specific organization. The Hay Guide Chart–Profile Method™ is a proprietary, standardized system that has been used by many different organizations as a job evaluation method. The Position Analysis Questionnaire (PAQ) is another standardized system that has been used for job evaluation purposes. It consists of approximately 200 items, referred to as *job elements*, that assess such aspects as how information is inputted in the job, mental processes used by the worker, relationships with others, and the job context (the physical and social environment). Research indicates that different job evaluation methods may produce different conclusions about the worth of jobs to the organization. Because the point-factor system is the most common method of job evaluation, most of what follows here is based on this approach.

DEVELOPING A POINT-FACTOR JOB EVALUATION SYSTEM

Briefly, organizations choosing to create a custom-tailored solution are likely to design a point-factor system using the following six steps. First, a committee is formed. Typically, this committee will include an expert in job evaluation, who may be an internal human resources manager or an external consultant, as well as other relevant parties (e.g., a union representative) and members who are familiar with the jobs to be evaluated. The next step is for the committee to determine what compensable factors will be used in the system. Simply stated, *compensable factors* are the underlying determinants as to why some jobs are paid more than others. Common compensable factors include mental demands, responsibility, education, and physical conditions. A clear, specific definition should also be provided for each compensable factor. The third step is to determine the relevant levels on each compensable factor. If education is a compensable factor, for example, the committee may determine that four levels are appropriate, such as high school diploma, 2-year college degree, 4-year college degree, and master's degree. There is nothing magical about the levels that are created. What is important is that the levels be appropriate for the jobs that will be evaluated.

In the fourth step, a total number of points is established for the system overall. Often, 1,000 points is used. The goal is to have a sufficient number of points to avoid a ceiling effect. The best way to understand the ceiling effect is to think of a scale to weigh people. If the scale does not go past 100 pounds, it will be impossible to accurately determine the weight of most adults.

Once the total number of points is determined, the committee must determine the number of these points to distribute to each factor. This step serves to *weight* the importance of each factor. Factors assigned more points will have a greater influence on the value of jobs than factors assigned fewer points. There are several different ways to determine the appropriate weights for each factor, including the rational approach and the statistical approach. In the *rational approach*, the committee would use logic, business strategy, or similar considerations in determining how much weight should be assigned to each factor. The *statistical approach* uses a quantitative formula to determine the relationship between the compensable factors and

what other, similar organizations are paying for key jobs. The statistical approach, then, attempts to link weights to external market pay. Research shows that the method of assigning weights may or may not affect the values that are ultimately assigned to the jobs.

Once the points are distributed to each factor, the next step is to assign points to each level on each factor. There are various ways to do this. One method is to assign the maximum points to the highest level on the factor (e.g., if master's degree was the highest level on education, and education was assigned 250 points, then master's degree would be granted 250 points). Next, a relatively small number of points (e.g., 30) might be granted to the lowest level on the factor (e.g., high school degree). A simple formula is usually devised to assign points to the levels in between the highest and lowest levels.

All that remains after creating the job evaluation system is to have subject matter experts (SMEs) review the appropriate job descriptions and related information about each position, and to determine the appropriate ratings on each compensable factor. Typically, several SMEs make independent ratings, after which their ratings can be compared. Where there are important differences in their ratings, discussion can ensue, until consensus is reached. For each job, ratings on each compensable factor are then added up and an overall rating is produced.

CRITICISMS OF JOB EVALUATION

In the last two decades, job evaluation in general and the point-factor system in particular have been criticized by some experts. One criticism is that the job evaluation process overemphasizes the importance of internal fairness (i.e., the notion that jobs should be paid fairly relative to each other) at the expense of external fairness (i.e., the notion that jobs should be paid fairly relative to what other organizations are paying for these jobs). A second criticism is that the complexity and opaque nature of job evaluation may create negative perceptions on the part of employees. Finally, some critics have argued that job evaluation reinforces a hierarchical, rigid organizational structure that lacks the necessary flexibility to rapidly adjust to environmental changes. These concerns have led some organizations to modify their job evaluation processes in a number of ways, including reducing the

number of compensable factors, changing the compensable factors, and tying the weights more closely to what other organizations are paying.

JOB INVOLVEMENT

Job involvement refers to a state of psychological identification with work—or the degree to which a job is central to a person's identity. From an organizational perspective, it has been regarded as the key to unlocking employee motivation and increasing productivity. From an individual perspective, job involvement constitutes a key to motivation, performance, personal growth, and satisfaction in the workplace. Job involvement contributes importantly to organizational effectiveness, productivity, and morale by engaging employees deeply in their work and making it a meaningful and fulfilling experience. People become involved in their jobs when they perceive in them the potential for satisfying salient psychological needs (e.g., for growth, achievement, meaning, recognition, and security).

Job involvement enhances individuals' work performance by motivating them to exert greater effort and use their creativity to solve problems and work intelligently. Job involvement and the benefits that flow from it result partly from personality and characteristics of the individual and partly from organizational context, job design, and supervisory behavior. Individuals who possess certain personality traits (e.g., internal locus of control, need for achievement,

work ethic endorsement) are likely to be predisposed to become job involved. On the other hand, situational factors such as job design, organizational and psychological climate, and management style all have important influences on employee job involvement. Job design factors appear to have a stronger influence on job involvement for individuals who have a stronger drive to satisfying higher-order psychological needs (i.e., higher-order need strength).

PROFILE OF THE JOB-INVOLVED INDIVIDUAL

Based on a systematic review of the voluminous research on job involvement, a profile of the personal characteristics of highly job-involved individuals emerges. In terms of personality traits, job-involved people tend to be high in both internal motivation and self-esteem and to subscribe to a work ethic consistent with the view that the experience of work has value as an end in itself. In terms of demographics, however, job involvement does not depend on age, gender, education, length of service to the organization, or salary.

Job-involved individuals find work meaningful and challenging, work at complex tasks employing a variety of skills, and see complete units of work through to their completion. They participate in the setting of performance standards and maintain positive relationships with supervisors who provide them with ample performance feedback. Beyond commitment to the immediate job, job-involved people are also strongly committed to work in general and career achievement and advancement.

People who are high in job involvement typically experience high job satisfaction, especially with the content of the work, which they find intrinsically satisfying. Their job satisfaction prevails even when their supervisor lacks consideration or is uncommunicative or autocratic. Job-involved individuals tend to have strong affective ties to the organization and, as a result, are less likely than others to consider leaving it.

In general, job involvement does not appear to entail systematic negative side effects, such as psychological, social, or physical maladies resulting from strong identification with one's job. Stress, anxiety, somatic health complaints, and work–family conflict do not appear to be systematically related to job involvement. On the other hand, job-involved individuals do not appear to be more satisfied with life in general than less job-involved individuals or

especially likely to be highly involved in other activities outside of work.

MEANS OF FOSTERING JOB INVOLVEMENT

As this profile of job-involved individuals suggests, promoting job involvement effectively can constitute a key to competitive advantage in the marketplace for organizations. Research suggests two closely related types of organizational factors that tend to promote job involvement and motivate effort toward achievement of organizational goals: psychological climate and human resource policies and practices.

Psychological Climate

Psychological climate refers to the manner in which organizational environments are perceived by their employees. More specifically, it refers to the way employees interpret features of the environment in relation to their own goals, values, and concerns for personal well-being. Two dimensions of psychological climate that have been strongly linked to job involvement are *psychological safety* and *meaningfulness*. Employees tend to perceive their work environment as conducive to the attainment of their needs and goals to the extent that they experience it as being psychologically safe and meaningful. Employee perceptions of the workplace as being psychologically safe and meaningful tend to be strongly and positively correlated, and both are strongly linked to job involvement and employee effort.

Psychological safety. Perceptions of the work environment as psychologically safe are rooted in three elements: supportive management, role clarity, and self-expression. A supportive management style allows employees to strive and possibly fail without fear of reprisals. It gives employees control over the methods they use to perform their work and allows them to bring their creativity to bear on work problems. Clear expectations and predictable, consistent work norms promote psychological safety and job involvement. And when employees feel free to express aspects of their individuality at work, they are likely to internalize the work role, personalize it, and treat it as a core aspect of the self-concept.

Meaningfulness. Employees perceive their work environment as psychologically meaningful when they

regard it as challenging, worthwhile, and rewarding. Individuals find their work particularly meaningful when they have a clear sense of the contribution it makes toward the attainment of organizational goals. Similarly, the perceived meaningfulness of work increases to the extent that employees perceive their work as challenging and conducive to learning and attainment of mastery. Also, receiving recognition and rewards commensurate with one's contributions tends to increase perceived meaningfulness of work.

Human Resource Policies and Practices

Human resource policies and practices are closely related to psychological climate and have important effects on job involvement, productivity, and organizational performance. Whereas psychological climate relates to individuals' perceptions of how the organizational environment affects their own goals, status, and well-being, human resource practices represent concrete policies and actions of the organization with respect to their employees. Research by Jeffrey Pfeffer and Mark Huselid indicates the following human resources practices as keys to high employee involvement motivation and performance:

Hiring selectively. Individuals differ in the values and attitudes they hold and express, as well as on a great variety of other characteristics. The companies that are most successful in promoting job involvement tend to attract rich pools of job applicants, from which they are able to select those who best reflect the goals and values of the organization. In essence, they endeavor to select the small proportion of applicants with the greatest predisposition to be highly job-involved, motivated, and productive.

Training. Firms that effectively promote job involvement tend to do an unusually thorough job of training employees. In these companies, training is ongoing and continuous and not limited to initial training and orientation to the organization.

Rewarding contingently and well. Companies that foster job involvement generally pay employees well and let them share in gains and profits made by the organization. This is true even of highly cost-conscious organizations that realize that employee productivity is a key driver of cost reduction. A contingent element of employee compensation contributes to employee

identification with the goals and fortunes of the organization.

Reducing status differences. A greater sense of teamwork and collective spirit in the organization results from minimizing status differences between executives and other employees. When executives forgo outsized compensation packages and conspicuous displays of status, employees lower in the hierarchy are able to identify more closely with them and, through them, with the organization.

Self-managed teams. Self-managed work teams incorporate and leverage an important motivational principle: that people identify closely with their peers and feel obligated to them by social norms and reciprocity. This means that some employees who might shirk in a hierarchical structure will not do so in the context of self-managed teams. Firms that foster high employee involvement often structure *all* work tasks as teamwork.

Sharing information. Employees are likely to identify to a greater extent with their work and organization when the organization freely shares information about its operations and performance. This information sharing highlights for employees their personal stake in the organization and gives them metrics by which they may steer their efforts in pursuit of organizational goals.

CONCLUSION

Job involvement—the extent to which individuals identify with their jobs and consider them central to their identities—constitutes a key to individual effort, motivation, performance, and satisfaction, as well as to organizational performance. Job involvement results from differences in individual predispositions and also from organizational characteristics, supervisory behavior, and job design characteristics. Thus, organizations can promote job involvement by selecting the right people, fostering a conducive psychological climate, and incorporating human practices and policies supportive of high employee job involvement. Such practices can hold the key to sustainable competitive advantage.

JOB KNOWLEDGE TESTING

Job knowledge is critical to successful job performance. Job performance can be viewed as being determined by one's *declarative knowledge* (knowledge of facts, rules, and procedures—a job's requirements), *procedural knowledge and skill* (knowing how and being able to do what the job requires), and *motivation*. In the job performance literature, *job knowledge* is the declarative knowledge of interest.

Job analysis studies often use job knowledge as an important job descriptor. A typical job analysis will identify the tasks performed by job incumbents, as well as the knowledge, skills, and abilities required to successfully perform those tasks. In this context, *knowledge* can be defined as the degree to which one has mastered a body of material (facts and theory) directly involved in the performance of a job. Competency studies also typically yield some knowledge-based competencies.

HOW IS JOB KNOWLEDGE MEASURED?

Although job knowledge is sometimes assessed using ratings (e.g., made by interviewers or supervisors), it is typically measured more directly and objectively with multiple-choice tests. Such tests are developed to

be content valid (i.e., to cover knowledge areas proportionately to their importance to the job as determined through job analysis). Many strategies can help ensure the quality of such tests. For example, a test blueprint (based on a job analysis) is developed to specify test content. The blueprint reflects the appropriate weighting of knowledge areas. Item-writing guidelines improve the readability and clarity of test items and help prevent “test-wise” examinees from performing inappropriately well on the test. It is also good practice to develop test questions that go beyond simple recall and definitions, instead requiring some amount of analysis or reasoning to answer the question. Some test developers use Bloom’s taxonomy as a framework to accomplish this. Another strategy is to use visual aids (e.g., illustrations, photos, graphics) to make the questions look more job-relevant and to limit the degree to which test scores depend on reading ability. Job experts also should review items for accuracy and collect judgments about the relevance and importance of each item to help document the content validity of the test.

Developers are increasingly using item formats other than traditional multiple choice because they can be easily administered and scored by computer. Such formats include multiple-response (e.g., check all that apply), matching, drag-and-drop, and ranking. Some of these formats efficiently cover more content than do traditional item formats, and varying the formats can make the test more engaging for examinees. It is important, however, to consider how to combine scores from different types of items so that the resulting total test score appropriately weights them. For example, how do you combine the score on a five-part matching item (in which examinees may be given partial credit for getting some, but not all, parts right) with the scores from several multiple-choice items (scored one point each) so that the reliability and validity of the total score are maximized? The answer might vary depending on the primary testing goal (e.g., maximizing content validity or correlations with other measures).

A job knowledge test can be developed, scored, and evaluated using classical test theory (CTT) and item response theory (IRT) strategies. Of these, CTT strategies have the advantage of being particularly useful for providing diagnostic information about items (e.g., percentage of examinees selecting each response option and option–total score correlations) that can be used to improve them through rewriting. Because they provide a common underlying metric,

IRT strategies are particularly useful if the test uses several item formats or if multiple forms of the test are required, but they require larger sample sizes to yield reliable information. If sample sizes permit, it is good practice to use both types of analytic strategies.

USING JOB KNOWLEDGE TO PREDICT PERFORMANCE

When hiring or promoting from a pool of experienced or relevantly educated candidates, an employer should consider including job knowledge as a component of the selection process. This is done most often in the context of job interviews. There is precedent for using tests of job knowledge for selection testing, but it can be expensive to develop and maintain a test for this purpose. Employers often look for relevant certifications (offered through either industry- or association-based testing programs) as a way to help gauge if individuals have sufficient job knowledge prior to hiring or promotion. When job knowledge is used to predict performance, it is important to consider what knowledge is required at entry versus that which can be acquired on the job—a distinction that can be made during the job analysis.

Little published research addresses the validity of job knowledge measures used for employee selection. One would expect the predictive validity of a well-designed multiple-choice test to be relatively strong when there is a strong correspondence between test content and job requirements. As with cognitive ability tests, however, job knowledge tests tend to exhibit Black–White race performance differences. The race differences for job knowledge tests, however, tend to be on the order of a half standard deviation, in contrast to the full standard deviation difference often observed on cognitive ability tests.

USING JOB KNOWLEDGE TO MEASURE PERFORMANCE

There are several relevant applications of job knowledge testing to measure performance. The primary application is probably seen in the vast number of credentialing (certification and licensure) testing programs offered. Job knowledge tests are also used as job performance criterion measures in criterion-related validation research.

Job knowledge tests, however, do not tell the whole story about an examinee’s capacity to perform a job. *Performance tests* is a term used for higher fidelity

assessments that require examinees to perform parts of a job in a simulated environment. The managerial assessment center is one form of such testing (typically used for selection and development) that has been around for a long time. There is a current surge of interest in using computer-based tests to develop more realistic performance measures. For example, the architect licensure examination not only includes multiple-choice questions, but also requires candidates to draft designs on the computer. Software certification testing programs are another example, as they also increasingly use high-fidelity simulations of work activities. It is important to recognize, however, that such tests still leave the motivational aspects of performance unmeasured. Performing well on a knowledge or performance test may yield a big part of the answer, but it is not the same as measuring job performance.

JOB PERFORMANCE MODELS

Almost all efforts of managers and human resources consultants have the objective of improving individual employee job performance, either directly or indirectly.

Efforts such as personnel selection or training are aimed at improving performance directly, whereas interventions in other organizational processes (e.g., culture, climate, or team processes by reducing conflict, and increasing coordination across organizational members) attempt to improve performance indirectly. The popular press is full of anecdotes of top executives who have lost their jobs because of incompetence in performing them. Given this state of organizational research and practice, it is necessary to have a clear understanding of what job performance is and the issues involved in its measurement. Job performance models have been developed to specify the content domain of job performance as well as to clarify the relationships among individual differences variables such as personality and organizational characteristics including reward systems to job performance. In this summary, we first examine the content domain of job performance, then consider some relevant measurement issues.

SPECIFYING THE CONTENT DOMAIN OF JOB PERFORMANCE

What constitutes job performance? This simple question becomes complex when we consider the nuances associated with it. Is it just what the organization has hired an employee to do (that is legitimate)? If so, a careful job analysis should provide the contours of what should be included when job performance of an individual is assessed. These aspects of job performance may include performance on tasks, communication, leadership, and avoiding counterproductive behaviors. Different models of job performance make distinctions among different aspects of performance. For example, one of the popular models of job performance distinguishes between task performance and contextual performance. *Task performance* is defined as the proficiency with which job incumbents perform activities that are formally recognized as part of their jobs, activities that contribute to the technical core of the organization. *Contextual performance* constitutes the activities that an individual incumbent performs that support the social environment in which the technical core must function. This distinction between task and contextual performance has been further developed in other models of job performance. Some of the models divide contextual performance to further subdimensions.

The literature on the dimensions of job performance has suffered from ambiguous conceptualizations.

Organizational researchers have used virtually any individual differences variable that could contribute to the productivity, efficiency, or profitability of the unit or organization as a measure of job performance. Even when appropriate measures have been used to assess aspects of job performance, consistent agreement about dimensions of job performance has not been easy to achieve. To understand which measures cluster together to assess a dimension of job performance, organizational researchers have collected data on the individual measures, as well as correlated and factor-analyzed such data. Yet decades of research along these lines have not converged on any unique solution, partly because it is infeasible to collect data on all measures from the same sample of job incumbents.

Recent years have seen the use of meta-analytic methods to cumulate data across several individual studies. This enables organizational researchers to assess the covariation of several job performance measures even though not all measures may be obtained from the same sample of incumbents. A comprehensive study that included all measures used in published articles in the *Journal of Applied Psychology* between 1917 and 2004 (see Further Reading) found that all the different measures were positively correlated. These positive correlations suggest that there is a common factor underlying all the different measures of job performance and the different dimensions into which job performance is sliced by different researchers and practitioners. The positive correlations also imply that in general, employees who perform well in one dimension are also likely to perform well in other dimensions. Thus, organizational interventions aimed to improve one dimension are likely to have a larger impact than usually acknowledged on other dimensions.

The fact that there is a general factor of job performance that underlies the different measures of job performance does not preclude or diminish the importance of individual dimensions or facets of job performance. What it implies is that depending on context and needs of the researcher/organizations, the content domain of job performance can be sliced in different ways. For an organization in a service industry, it may be pertinent to make distinctions between customer friendliness and working well with coworkers, treating them as two separate dimensions. To assess employee job performance in an industrial manufacturing plant, it may very well make sense to combine the two dimensions as one overall dimension of

interpersonal competence. Different conceptualizations and dimensional views of job performance are relevant for different organizational interventions (e.g., selection versus training). This renders controversies of which set of job performance dimensions is correct moot.

Recognizing that the different sets of dimensions postulated are dependent on context and purpose of measurement, we can employ a two-dimensional grid to classify the different taxonomies of job performance dimensions postulated in the extant literature. The first dimension of this grid distinguishes whether the taxonomy under consideration is developed for a particular job/occupation or for being applicable across occupations. For example, one taxonomy of job performance dimensions focuses exclusively on retail industry entry-level workers and proposes the following nine dimensions of job performance: adherence to rules, industriousness, thoroughness, schedule flexibility, attendance, off-task behavior, unruliness, theft, and drug use. Although this set is appropriate for retail industry employees, schedule flexibility may not be a relevant dimension in another occupation. In contrast, another taxonomy of job performance, developed to be applicable across occupations, proposes the following eight dimensions into which the job performance content domain can be sliced: job-specific task proficiency, non-job-specific task proficiency, written and oral communication competence, demonstrating effort, maintaining personal discipline, facilitating team and peer performance, supervision, and administration. The taxonomies that are specific to occupations are richer in context-specific information yield, whereas the second type described have the advantage of generalizability. It should, however, be noted that regardless of whether the taxonomies are occupation specific or applicable across organizations, the dimensions are positively correlated, suggesting the presence of a common factor of job performance across all dimensions. In fact, the general common factor usually explains as much as 60% of the variance in each dimension.

In addition to classifying the taxonomies as either occupation-specific or not, we can also group the taxonomies as to whether they focus on specific aspects of performance or on the whole domain of job performance. For example, several taxonomies of counterproductive work behaviors have been proposed in recent years. The goal is not to define the entire content domain of job performance but to home in on specific aspects of performance. Overlaying this

classification of taxonomies with the previous classification (occupation-specific versus across occupations) results in a four-cell classification of taxonomies. This two-dimensional grid serves the useful purpose of summarizing the numerous taxonomies of job performance content postulated in the literature.

MEASUREMENT ISSUES IN JOB PERFORMANCE ASSESSMENT

Given the centrality of job performance assessment to several high-stakes decisions in organizations (selection of personnel, merit pay, legal defense of organizational policies, etc.), accurate measurement of job performance is critical. Measures of job performance can be objective, organizational records of units produced, errors made, absences, promotion rates, accidents, or turnover. Alternatively, measures of job performance can be subjective, judgmental evaluations that can be either rankings or ratings. The judgmental evaluations can be made by supervisors, peers, or subordinates, or even by the employees themselves. Sometimes, organizations obtain judgmental evaluations from customers. The purpose of the assessment (e.g., deciding merit pay raises) may render some evaluation sources (e.g., self-ratings) untenable. A voluminous literature on multisource feedback or 360-degree feedback addresses the relative merits of different evaluators and argues for an integration of the different perspectives for a comprehensive evaluation of an individual employee.

Given that specific dimensions of job performance can be evaluated by different sources (supervisors, peers, etc.), a natural question arises as to the equivalence of the different sources in evaluating a particular job performance dimension (e.g., leadership). That is, do supervisors and peers mean the same thing when evaluating an employee as demonstrating good leadership? One hypothesis is that the different sources emphasize different behaviors, observe different behaviors, and mean different behaviors when rating an employee's leadership. In this example, supervisors may rate employees' leadership based on how well they get the task done through subordinates, whereas peers may rate the employee's leadership based on how well the employee coordinates with other colleagues. If this hypothesis is correct, the correlation between leadership ratings provided by supervisors and leadership ratings provided by peers for a set of employees should correlate less than perfectly. Recent cumulative research suggests that although the observed

correlation is less than perfect, the magnitude of the relationship is affected by unreliable measurement and once corrections for unreliability are applied, the corrected correlation is much closer to 1.0 than previously believed. Thus, it appears that the different sources (peers, supervisors, etc.) rate the same dimension, albeit with emphasis on different observable behaviors. The fact that different sources of raters are rating the same dimension does not detract from the merit of multisource assessments. An analogy with test construction is useful here. A test of intelligence will have several items, and integrating responses across items we get a better (i.e., more comprehensive coverage of the content domain of intelligence) and more reliable assessment of intelligence. Similarly, multisource assessments ensure comprehensiveness in coverage of behaviors under consideration and enhance the reliability of the composite evaluation.

Another measurement issue in job performance assessment is definitional in nature. Some researchers have argued that job performance measures should include only behaviors and not outcomes of behaviors. Thus, the efforts made by an employee (e.g., number of contacts made with potential customers) should be evaluated, but the outcomes (e.g., number of units sold) should not be. The reasoning for this distinction relies on the control an individual employee has on behaviors versus outcomes. The argument is that an individual's performance should be evaluated based on what is under the control of the employee. However, this issue of control is relative. On one hand, one could argue that the number of papers written by a professor is part of job performance but the number of papers published is not (as this depends on several factors outside the control of the professor). On the other hand, even the number of papers written is not strictly under the control of the professor. Given this endless circle of arguments, it is preferable if job performance is defined as both evaluable behaviors and outcomes.

Other measurement issues are likely to come to the forefront of debate in the coming years. Almost all taxonomies of job performance dimensions do not take into account the temporal relationships across the dimensions. For example, interpersonal competence at time 1 can result in better productivity at time 2. Exploring the dynamic relationships among job performance dimensions is not the same as the issue of criterion dynamicity. *Criterion dynamicity* refers to the hypothesis that individuals will improve in the performance of a dimension over time. Cumulative

research shows that although there are mean changes in performance over time (i.e., people improve with experience), the relative rank ordering of individuals on performance on that dimension stays fairly constant over time.

We close this section on measurement issues with a note on the reliability of job performance assessments. *Reliability* is the consistency of measurement, and depending on the answer to the question “Consistency over what?” there are several types of reliabilities. When a job performance item is measured at two points in time (assuming no change in true performance levels), the correlation indexing the consistency across the two points in time is the test–retest (or rate–rerate) reliability. When a job performance dimension is assessed with several items, consistency across the items is captured by the alpha coefficient. When two raters rate the performance of a set of employees, the interrater reliability captures the consistency across raters. Cumulative research has shown that there is a large idiosyncratic component in each rater’s ratings. To the extent organizational researchers and practitioners are interested in the shared (across raters) component of job performance assessments, interrater reliabilities are the appropriate reliability coefficients to use.

CONCLUSIONS

Job performance is a central variable in organizational research and interventions. Several models of job performance have been developed to slice the content of job performance into different sets of dimensions. The different models can be placed into one of the four cells of a two-dimensional grid that takes into account (a) whether the model is occupation specific or applicable across occupations and (b) whether the entire domain of job performance or a specific section is targeted. Despite the different ways the job performance domain can be partitioned into dimensions, all dimensions are positively correlated, suggesting a common underlying factor across all job performance dimensions. The measurement of job performance raises several issues, such as the temporal relationships across dimensions and choosing the appropriate reliability coefficient. Given the large idiosyncratic component in individual rater ratings, interrater reliability coefficients should be assessed. Cumulative research also suggests (a) equivalence of different sources of ratings and (b) lack of criterion dynamicity. Job

performance assessments are critical in high-stakes decision making in organizations, and continued research is likely to improve existing job performance models.

JOB ROTATION

The term *job rotation* is used to describe two different rotation processes. First, *job rotation* is used to describe the process of workers with high physical

demands or highly repetitive tasks alternating or rotating from these highly physically demanding tasks or from repetitive tasks to other tasks. The rotation may take place to expose the worker to less physical strain, or to enhance the motivating potential of the overall job. In addition, this type of job rotation is also meant to reduce boredom, fatigue, and related injuries. Second, *job rotation* is used to describe an employee's lateral movement within a company to a different job title or a different department, with the objective of enhancing the employee's professional development through exposure to a new set of knowledge, a different job, and a different department. Employees on different organizational levels can rotate jobs; however, job rotations are more common among professional employees and managers than among nonprofessional workers. Generally, job rotation does not include promotions or advancements, which are nonlateral movements that come with increased responsibilities and usually with differences in pay grade.

OBJECTIVES OF THE TWO TYPES OF JOB ROTATION

Task Rotation

Job rotation as task rotation bears similarities with job enrichment and other job redesign efforts, which are meant to enhance the motivating characteristics of work and reduce biological, psychological, and physiological strain on the employee. The reduction of work-related accidents and injuries related to fatigue and boredom is another objective frequently pursued by organizations implementing job rotation that encompasses employees switching tasks more than they used to. As job rotation is meant to enhance the perceived meaningfulness of work for employees, organizations also expect enhanced internal and external customer satisfaction from implementing job rotation practices that contain task rotation.

Position or Department Rotation

Job rotation as lateral rotation to a different job or department has the objective of advancing the breadth of exposure the employee has to different components of his or her organization. Employees engaged in job rotation are meant to accumulate experiences, business knowledge, and better organizational networks. In addition, job rotation is supposed to contribute

to enhanced employee motivation, reduce boredom and fatigue, and lower the likelihood of accidents in monotonous jobs. From an organizational perspective, it has been argued that job rotation can enhance the company's knowledge about the employee's potential, knowledge, abilities, and perspectives and can lead to intellectual capital accumulation.

INVOLVEMENT IN JOB ROTATION

Task Rotation

Job rotation that involves task rotation is, in most organizations, limited to manufacturing and low-level administrative positions. The complexity and training requirements for most higher level jobs, as well as the lower monotony, along with the absence of stressors related to physical and mental fatigue and boredom, have precluded most complex jobs (e.g., most professional jobs) from involvement in task rotation processes.

Position or Department Rotation

The number of companies in Western societies using job rotation to laterally move employees into different jobs or organizational divisions has increased in the past decades. Large companies are more likely to have elaborate job rotation programs involving about 50% of their employees, whereas job rotation is less prevalent at organizations with fewer than 50 employees. Individuals engaged in job rotation programs are more likely to be younger, have less tenure, and be more ambitious than employees who are not involved in job rotation. Research also demonstrates that high-performing employees are more likely to obtain placement in a job rotation program than are individuals not performing according to expectations.

OUTCOMES OF JOB ROTATION

Task Rotation

Although organizations expect more benefits than costs from job rotation programs that involve task rotation, research indicates that rotating individuals through several tasks is beneficial to their satisfaction only if the enlargement of the employee's job through job rotation contains knowledge enlargement rather than just task enlargement. *Knowledge enlargement* pertains to the addition of job elements that require

enhanced understanding of procedures, rules, and policies. *Task enlargement* is defined as the addition of other simple tasks that do not require deeper understanding of processes. Longitudinal studies found consequences of mere task enlargement to include lower satisfaction levels, lower chances of error detection, and decreased customer service. In contrast, knowledge enlargement was found to lead to higher satisfaction levels, reduced perceptions of mental underload, and increased likelihood of error detection. Overall, the consequences of job rotation from an employee perspective are more complex than researchers initially expected: Although some job rotation efforts were found to have positive consequences in terms of reducing muscle strain and physiological tension, not all job rotation led to positive outcomes in employee well-being, motivation, and health.

Position or Department Rotation

Overall, both organizations and employees benefit from job rotation that pertains to lateral moves of employees to different job titles or divisions, but both also incur some costs. From an employee perspective, long-term salary growth and promotion are among the desirable outcomes of job rotation. In addition, employees involved in job rotation gain increased knowledge and skills, with job rotation leading to higher skill improvement in the business domain than in areas such as technical or administrative skills. Nonrotating employees in organizations that have job rotation were less satisfied than rotating employees. Employees involved in job rotation had more positive job attitudes than those not engaged in job rotation—they were generally found to be more satisfied, committed, and involved than nonrotating employees at the same company. Costwise, job rotation was found to lead to increased workloads among rotating employees and to add a financial burden for the organization (e.g., necessity of moving employees to different locations).

JOB SATISFACTION

Job satisfaction refers to the overall feelings one has and the evaluation one makes about one's job. People with high job satisfaction experience a pleasurable or positive emotional state when they think about their job or job experiences. In simple terms, they like their jobs. Since early studies in the 1930s, job satisfaction has become one of the most widely investigated concepts in the field of industrial/organizational psychology. It is a valuable outcome in its own right but also a driver of other important individual and organizational outcomes. The importance of this concept is reflected in its central role in numerous theories, such as those concerning job design, leadership, and employee withdrawal.

DEFINING AND MEASURING JOB SATISFACTION

Job satisfaction is traditionally defined as a pleasurable or positive emotional state that results from one's appraisal of one's job or job aspects. This definition includes both one's affective reactions to one's job (feelings) and one's cognitive evaluation of the job (thoughts). There is controversy about whether job satisfaction should be considered as the interplay of both one's thoughts and feelings, as implied in this definition, or whether the cognitive and affective aspects should be separated into distinct dimensions. Those advocating the latter approach cite studies showing that cognitively oriented measures of job satisfaction predict different behaviors to affect-based measures of job satisfaction.

Although the definition of job satisfaction is in some dispute, both sides agree on the need to align the measurement of job satisfaction with the definition. Defining job satisfaction as, say, an affective response but assessing it as an evaluation leads to confusion. A further issue to consider when measuring job satisfaction is its focus. One can assess how satisfied one is with one's job as a whole, or one's global feeling about the job. A typical question would be: "Overall, how much enjoyment do you find in your work?" An alternative to this global approach is to assess and sum up satisfaction with facets of the job, such as satisfaction with one's pay, one's colleagues, the nature of the work, and the supervision. Research shows that overall global satisfaction is something different from a combination of facet satisfactions. Moreover, satisfactions with different facets are often not highly related. For example, one can be very satisfied with colleagues but highly dissatisfied with promotion prospects. If one is trying to understand the overall effect of jobs, then global ratings are usually the best choice. However, a facet approach is more diagnostic if the assessor wants to know how to improve satisfaction in a particular situation.

CAUSES OF JOB SATISFACTION

There are three well-recognized general causes of job satisfaction: the situation, the person, and the interaction between the situation and the person.

Situational Causes

By far the greatest attention has been given to situational influences on job satisfaction. An early theory of situational influences was Frederick Herzberg's two-factor theory, which proposed that intrinsic job factors such as the work itself (*motivators*) caused satisfaction, whereas extrinsic "hygiene" factors external to the job (e.g., pay) caused dissatisfaction. Although appealing, this theory has not stood the test of time. In fact, both types of factors contribute to both job satisfaction and job dissatisfaction.

A more enduring theory that focuses on situational causes of job satisfaction is the job characteristics model (JCM). This model proposes that there are certain intrinsically motivating features of a job that lead to job satisfaction as well as other positive work outcomes. The theory focuses on five work characteristics:

- *Task identity*: degree to which one can see one's work from beginning to end
- *Task significance*: degree to which one's work is seen as important and significant
- *Skill variety*: extent to which job allows employees to do different tasks
- *Autonomy*: degree to which employees have control and discretion for how to conduct their job
- *Feedback*: degree to which the work itself provides feedback for how the employee is performing the job

According to the theory, and as subsequently demonstrated in both meta-analyses and rigorous longitudinal field studies, jobs that are enriched to provide these core characteristics are more satisfying and motivating than jobs that do not provide these characteristics.

A theory that has parallels with the JCM is the demand-control model of strain, which proposes that job demands and job control work together to affect job strains, including dissatisfaction. There is good evidence that people are more satisfied if they have jobs with high control and with moderate levels of demands. However, there is mixed support for the more specific "buffering" hypothesis that has often been articulated in accounts of this model, which holds that job control reduces the dissatisfying effects of high demands. This is a compelling proposition, because it implies one can increase job demands without detriment to employee well-being so long as employees also have high control.

Practically, the implication of both the JCM and the demand-control models is that one can improve job satisfaction by changing job characteristics, or job redesign. For example, job enlargement involves expanding the variety of tasks associated with a particular job; job enrichment involves increasing the level of autonomy in a job, such as by allowing individuals to make decisions previously made by supervisors; and introducing self-managing teams involves increasing autonomy for a team of individuals, such as by allowing the group to allocate tasks among themselves.

The JCM and the demand-control model both focus on the influence of core intrinsic job characteristics, and evidence generally shows that it is the nature of work itself that most affects job satisfaction. However, job satisfaction and dissatisfaction are also affected by other work experiences, such as exposure to sexual harassment and injustice, career development opportunities, constraints that inhibit performance (e.g., malfunctioning equipment), clarity about

roles, conflicting role expectations, difficulties arising from juggling work and family responsibilities, and the presence of supportive leadership. Interestingly, the amount an individual is paid has little influence on job satisfaction, although the perceived fairness of that level of pay can be very important. Group-level job characteristics (such as how much control the team has) and organizational-level characteristics (such as the overall culture) can also affect job satisfaction. At an even higher level of analysis, cultural factors also appear to affect job satisfaction, although we currently know relatively little about what causes differences in job satisfaction across countries.

PERSONAL CAUSES

Job satisfaction also depends on people's temperaments and personalities. For example, some individuals will be dissatisfied with their jobs no matter what the nature of their work. This idea was introduced in the 1930s when an early study suggested job dissatisfaction might be the product of nonadjustive emotional tendencies, but the idea then lay dormant until recently.

In the past few decades, two broad approaches to the investigation of dispositional sources of job satisfaction have emerged. The first, an indirect approach, shows that job satisfaction scores can be quite stable over long periods of time (e.g., 5 years), even when individuals change employers and occupations. The implication is that stable individual differences in personality cause the long-term consistency in job satisfaction. However, the problem with this approach is that other factors might cause this stability. For example, some people might consistently choose good jobs, and some people might always choose bad jobs, resulting in stable levels of job satisfaction over time.

A second and more direct approach is to relate dispositional variables to job satisfaction, thereby providing insight into what personality traits might be important. One such trait is *affective disposition*. Individuals high in *positive affectivity* (who are prone to describe themselves as cheerful, enthusiastic, confident, and active) tend to experience high job satisfaction, whereas those high in negative affectivity (who are prone to experience negative mood states such as anxiety, depression, and guilt) tend to report low job satisfaction. For example, one's positive or negative affectivity in teenage years can predict job satisfaction at 54 to 62 years of age. Individuals who are emotionally stable with high levels of general

self-confidence and feelings of positive self-worth (referred to as a *positive core self-evaluation*) also tend to experience higher job satisfaction than those who have a more negative core view of themselves.

Recent research has tackled the question of why these personality characteristics affect job satisfaction. For example, some evidence suggests that individuals who have a positive view of themselves tend to seek out and obtain more enriched and satisfying jobs. Individuals might also interpret job circumstances differently according to their disposition. For example, individuals high in negative affectivity might have a higher threshold for perceiving and responding to positive stimuli.

In addition to personality or disposition as causes of job satisfaction, researchers have sought to understand whether demographic variables have a role. Although the findings are inconclusive for gender and race, there is good evidence that general job satisfaction increases with age, with some studies suggesting a tail-off after about 45 years of age. This age effect might be because older workers have developed more realistic expectations about work, or because they have more skills than younger workers and therefore are able to obtain better jobs.

PERSON X SITUATION CAUSES

Several theories propose that job satisfaction derives from the interaction between the person and the situation. For example, the job characteristics model proposes that job enrichment is more strongly related to job satisfaction for individuals who prefer challenge and interest in their job. There is reasonable support for this proposition.

A further example of an interactive theory is the Cornell model, which proposes that job satisfaction is highest when individuals receive a high level of outputs from their job (e.g., pay, status, working conditions) relative to their inputs into the work role (e.g., time and effort). The model recognizes that the value an individual places on inputs and outputs can affect this equation. For example, if unemployment is high, and hence there is high competition for scarce jobs, individuals will see their inputs as less valuable. All else being equal, they are therefore likely to report greater job satisfaction. The value-percept theory is another interactive approach that has generally been supported. This theory proposes that individuals are likely to be satisfied if the things they find important

(their values) are fulfilled. In other words, discrepancies between what is desired and received are dissatisfying only if the job facet is important to the individual.

OUTCOMES OF JOB SATISFACTION

Job satisfaction is often seen as an important outcome in its own right. From a social and humanitarian perspective, there is obvious value in having a society in which people have positive views about their work and feel they are treated with dignity and respect. After all, individuals spend up to one third of their waking hours in the workplace. In addition, however, job satisfaction can affect important personal and organizational outcomes. Some of the most well-established ones are discussed next.

Life Satisfaction and Health

For a small number of individuals, job and life experiences are segmented and have little effect on each other. For an even smaller group, the compensation model applies, meaning that individuals seek to compensate for a dissatisfying job by looking for fulfillment outside of work. For most individuals (around 70%), however, job experiences spill over and affect their lives more broadly. This spillover model is supported by evidence that job satisfaction has a moderately strong positive correlation with one's overall life satisfaction. It seems that how one feels and/or thinks about one's job tends to affect how one feels and/or thinks more broadly. The reverse is also true: One's broader life satisfaction can affect job satisfaction.

In terms of health, there are clear links between job satisfaction and mental health, such as depression and burnout. *Burnout* is a distressed emotional state experienced on the job, such as feeling emotionally exhausted and feeling a reduced sense of personal accomplishment. Job dissatisfaction has also been associated with physical symptoms such as headaches, although the methodological limitations of most studies in this area (e.g., an overreliance on self-reported assessments of health) preclude any conclusion about causality at this stage.

Job Performance and Other Important Organizational Behaviors

It is intuitively appealing to believe that the happy worker is also a productive one. However, in the

mid-1980s, a very influential meta-analysis of the literature suggested a relatively low correlation (.17) between job satisfaction and performance. At this point, the effect of job satisfaction on performance appeared trivial.

More recent evidence challenges this conclusion. First, job satisfaction has been shown to be more strongly predictive of performance when organizational citizenship behaviors are included as part of performance. *Organizational citizenship behaviors* are voluntary acts to help coworkers and employers. It makes sense that individuals who are happy and satisfied at work are more likely to engage in such voluntary behaviors. Second, a more recent and rigorous meta-analysis of correlations between job satisfaction and individual performance showed a moderate-sized correlation between these variables (.30), which was even higher for complex jobs. It is likely that more complex jobs allow individuals more autonomy and latitude to act on their satisfaction. Third, studies conducted at the organizational level of analysis (which, for example, compare the average satisfaction of a company and its performance with the average satisfaction and performance of other companies) also suggest a positive and nontrivial relationship between job satisfaction and organizational performance indicators such as market share and profit.

In addition to job satisfaction promoting positive work behaviors, there is evidence that job dissatisfaction promotes negative behaviors within organizations. Thus, dissatisfied employees are more likely than satisfied employees to engage in counterproductive acts in organizations (e.g., theft, aggression, sabotage), particularly if they believe they have low control at work. Dissatisfied employees are also more likely to engage in withdrawal—that is, job avoidance behaviors such as quitting, coming in late, or being absent. It appears individuals will seek to escape a dissatisfying job and that if they can't escape permanently by leaving the job entirely, then they will escape temporarily by being late or being absent. The evidence is particularly strong that dissatisfied individuals are more likely to leave their job altogether, especially if there are alternatives (e.g., if unemployment is low, individuals are more likely to leave their job if they are dissatisfied than they are when unemployment is high).

The relationship between job satisfaction and absence is smaller and more inconsistent, despite the fact that job satisfaction features prominently in

theories of absence. In part, this weaker relationship reflects the fact that people are absent for many reasons (e.g., illness, sick children), and it also reflects methodological challenges (e.g., often there are a few employees with very high absence rates, which affects the statistical distribution of absence). Recent evidence shows that job satisfaction is most likely to predict withdrawal when the various behaviors are considered together as part of a pattern, rather than when focusing on any single indicator of withdrawal.

SUMMARY

How much we like our jobs—our job satisfaction—is a critical concept in the study of work. Job satisfaction is likely to result in a number of positive benefits, both for individuals (their well-being, mental health, and life satisfaction) and for organizations (better performance, more citizenship, less counterproductive behavior, and less withdrawal). Importantly, job satisfaction can be changed. Even though our job satisfaction is in part a product of who we are, regardless of our job or work situation, our job satisfaction is also significantly affected by the work situation. In many instances, the work environment can and should be changed, such as by reducing excess workload, increasing levels of job autonomy, or introducing practices to reduce home–work conflict. Such change initiatives are especially likely to be successful in raising job satisfaction if one takes into account individual values and personality in this process.

JOB SATISFACTION MEASUREMENT

Job satisfaction may be measured for a variety of reasons. For example, a company may measure job satisfaction over time to assess trends in employee attitudes or reactions to a new policy or organizational intervention. Assessing job satisfaction might also serve a diagnostic purpose, identifying those aspects of the job with which employees are dissatisfied. As a last example, companies might measure job satisfaction to predict other important attitudes or behaviors (e.g., job turnover). In all instances, a useful measure is important.

WHAT MAKES A MEASURE OF JOB SATISFACTION USEFUL?

Is It a Good Measure?

Good measures are reliable (i.e., levels of job satisfaction that are in fact consistent over time demonstrate similar satisfaction scores), valid (i.e., the measure provides a pure measure of job satisfaction), discriminating (i.e., the measure of job satisfaction is equally sensitive to low and high reported levels), and comparable (i.e., the measure allows you to compare job satisfaction scores across groups). Developing a good measure requires significant expertise and

resources and should be undertaken by individuals with strong backgrounds in psychometrics and statistics. The unfortunately common strategy of writing a few items and assuming they provide a measure of job satisfaction is inappropriate. Without evidence of quality, homegrown measures may yield erroneous interpretations and conclusions.

Is the Measure Appropriate for Your Purposes?

Multiple good measures of job satisfaction are available, so the choice depends in part on purpose. For example, is the measure of job satisfaction easy to administer, score, and interpret? Does it support the types of interpretations needed (e.g., overall job satisfaction versus different areas or facets of job satisfaction)? Is the reading level appropriate? Is the measure available in different languages so that organizations can assess satisfaction in the first languages of employees throughout the world? Finally, how much does it cost? Answers to these questions will be very helpful in selecting the best possible measure of job satisfaction for the purpose at hand.

VARIATIONS IN MEASURES OF JOB SATISFACTION

Quantitative Versus Qualitative Measures

Quantitative measures of job satisfaction, based on numerical ratings assigned to closed-ended response items, are by far the most commonly used types of measures (and are preferred, given the characteristics of a good measure identified above). Structured interviews, content coding of open-ended response items, and other qualitative measures of job satisfaction offer an enriched interpretation of findings obtained from quantitative measures. They are not recommended in place of quantitative measures, because they do not lend themselves to drawing comparisons across groups of employees or organizations.

Overall Versus Facet

Given the different purposes for measuring job satisfaction, both overall and facet measures have been developed. *Overall* measures provide a global assessment of job satisfaction and may require the summation of several general items, the summation of items measuring a broad set of facet areas of satisfaction, or

both. *Facet* measures focus on the assessment of satisfaction with different aspects of the job, which typically include dimensions such as supervision, pay, coworkers, and the work itself. Unlike an overall rating, facet measures yield a diagnostic profile of satisfaction so that one may identify particular areas that might be high or low.

Single Versus Multiple Item Measures

It is appealing to think that a well-written single item will be a good measure of overall job satisfaction (e.g., "Overall, I am satisfied with my job") or different facets of job satisfaction (e.g., "My level of pay fails to meet my needs and expectations"). They would be short and easy to complete, score, and interpret. Unfortunately, they typically have low reliability and validity. Reviews of published measures of job satisfaction (see Further Reading) commonly include multiple items.

General Versus Occupation-Specific Measures

Most measures of job satisfaction are developed for use across occupations. These general measures are useful for most organizations. However, measures of satisfaction have been developed for specific employee populations (e.g., nurses, human service employees). Although such measures may be more sensitive to the particular issues of a profession or job grouping, they are not available for many occupations and prohibit cross-occupational comparisons.

LOCATING MEASURES OF JOB SATISFACTION

Mental Measurement Yearbook

The Mental Measurement Yearbook (MMY) is a serial publication available in most libraries and provides a somewhat comprehensive listing of a broad range of tests and measures. The MMY solicits external reviews by established researchers who critically evaluate new measures. However, with its broad range, it does not provide an all-inclusive listing of established measures of job satisfaction.

Compendia of Satisfaction Measures

There are compendia of job attitude measures, a number of which are included in the Further Reading

section at the end of this entry. Although some are dated and may not include recently developed measures of job satisfaction, compendia often provide summaries and recommendations that may help one choose among the many published measures.

Test Publishers

A large number of test publishers market measures of job satisfaction that were developed in-house by the publishers' professional staffs or that provide the marketing support for measures of job satisfaction developed by others. Unfortunately, there is no easy way to identify test publishers who specialize in measures of job satisfaction.

World Wide Web

Currently, Internet search engines can be used to locate Web pages that may provide information about measures of job satisfaction. Also, the electronic database PsycINFO includes more than 1,900 behavioral science journals. Unfortunately, current features of the search interface make it challenging to discriminate between articles about measures of job satisfaction and those that simply measure the construct.

Exemplar Measures of Job Satisfaction

Although a large number of measures of job satisfaction are available, and some may be more relevant given the specific purpose, a few measures are discussed here based on their excellent reputations as well-designed and useful.

Faces Scale

The Faces Scale, developed in the 1950s, measures overall satisfaction using a single, nonverbal item. Eleven faces appear along a continuum from a broad smile to a deep scowl, and respondents are asked to circle the face that best describes their overall job satisfaction. Despite the admonishments earlier in this discussion against using single-item measures, the Faces Scale has been shown to be a remarkably good measure of satisfaction with the job overall. It is simple to administer and score. It is unclear whether it is effective in cross-cultural situations. It can be

administered across a broad range of employees, although it may be less accepted by midlevel management or above. Overall, the Faces Scale is a quick and simple measure of overall job satisfaction.

Minnesota Satisfaction Questionnaire

The 20-item short form version of the Minnesota Satisfaction Questionnaire (MSQ) was developed in the 1960s to provide a comprehensive assessment of general job satisfaction. Each of the 20 items starts with a common *stem* ("On my present job, this is how I feel about:") and taps into some specific aspects of the job (e.g., "... Being able to keep busy all the time"; "... The working conditions"). Each item is scored on a five-point *very dissatisfied*–*very satisfied* scale and summed in an unweighted fashion for an overall measure of satisfaction. Item subsets can also be summed to provide scores on intrinsic and extrinsic satisfaction, but recent research questions the quality of these two submeasures. Decades of accumulated research suggest that the MSQ provides a good measure of overall satisfaction.

Job Diagnostic Survey

The Job Diagnostic Survey (JDS) measures job characteristics but also includes a five-item measure of overall job satisfaction. The items include positively worded statements (e.g., "Generally speaking, I am very satisfied with this job") as well as reverse-scored items (e.g., "I frequently think about quitting this job"). The items are scored on a seven-point *disagree strongly*–*agree strongly* scale and are summed in an unweighted fashion for an overall measure of satisfaction. The JDS job satisfaction scale is easy to administer and score and has been found to provide a good assessment of overall job satisfaction. However, two items focus on quitting, a related but different concept. Therefore, it may not be a pure measure of job satisfaction.

Facet-Specific Job Satisfaction

The Facet-Specific Job Satisfaction (F-SJS) measure includes 33 items to measure six distinct features of the job: comfort (e.g., "The hours are good"), challenge (e.g., "The work is interesting"), financial rewards (e.g., "The pay is good"), relations with coworkers (e.g., "The people I work with are friendly"),

resource adequacy (e.g., “My responsibilities are clearly defined”), and promotions (e.g., “Promotions are handled fairly”). Responses are scored using a four-point *very true–not at all true* scale, providing six distinct scale scores; the items can also be summed to provide an overall measure of job satisfaction.

Job Satisfaction Survey

Originally developed for use in human service organizations, the Job Satisfaction Survey (JSS) includes 36 items that are scored on a six-point *disagree strongly–agree strongly* scale. Scored items are summed in an unweighted fashion for an overall measure of satisfaction. There are also nine facet scores: pay (e.g., “I feel I am being paid a fair amount for the work I do”), promotion (e.g., “I am satisfied with my chances for promotion”), supervision (e.g., “My supervisor is unfair to me”), fringe benefits (e.g., “I am not satisfied with the benefits I receive”), contingent rewards (e.g., “When I do a good job, I receive the recognition for it that I should receive”), operating procedures (e.g., “I have too much paperwork”), coworkers (e.g., “I enjoy my coworkers”), nature of work (e.g., “I feel a sense of pride in doing my job”), and communication (e.g., “Communications seem good within this organization”). Score distributions from previously surveyed employees (primarily from public-sector and medical/ mental health organizations) are available online for comparison purposes.

Job Descriptive Index/Job in General

The Job Descriptive Index (JDI), first published in 1969 and revised in 1985 and 1992, is commonly cited as the most carefully developed and most frequently used measure of job satisfaction. It has been translated into a variety of languages, and national norms have been developed (and are regularly updated) to allow both within- and cross-organization comparisons. The JDI measures five facet areas of satisfaction that have been identified as important across many organizations: work itself, pay, opportunities for promotion, supervision, and the people with whom one works. The scale includes a total of 72 adjectives or short phrases, and respondents are asked to mark a “Y” (Yes, it describes my job), an “N” (No, it does not describe my job), or “?” (Cannot decide). The Job in General (JIG) measure was developed in 1989 to

provide a complementary measure of overall job satisfaction to the JDI. The JIG includes 18 items, using the same item design and response format as the JDI. The JDI and JIG can be completed by individuals with a third-grade or higher reading level and together take no more than 15 minutes to complete. More recently, abridged versions of the JDI and JIG have been developed in response to the desire for shorter measures that still include a broader range of scales and items. The Abridged Job Descriptive Index (AJDI) contains a total of 25 items; the Abridged Job in General (AJIG) measure contains 10 items. Efforts are under way to offer online administration, scoring, interpretation, and report writing that are completely automated, a service that may be particularly helpful for midsized organizations that lack the expertise to do their own survey work.

JOB SEARCH

Job search can be defined as the specific activities through which effort and time are expended to acquire information about labor market alternatives. Stated more simply, job search is the pursuit of employment. There are few well-developed models of job search. This scarcity results in part from the tendency for organizational scientists to focus on job seekers after job alternatives have been generated. Thus job search is generally viewed as part of a larger model encompassing the job evaluation and choice processes. Specifically, job alternatives generated through job search are evaluated to arrive at a job choice decision. Such decisions include choosing among job alternatives, remaining with the current employer, or withdrawing from the labor market.

MEASURING JOB SEARCH

Job alternatives generated through job search activity are a function of (a) the sources used and (b) the level of intensity in pursuing those sources. Accordingly, there are two typical approaches to measuring job search. The first approach is to examine the number of behaviors (e.g., prepare résumé, telephone a prospective employer, fill out a job application) an individual engages in over a period of time, where a higher number indicates greater search activity. An alternative approach is to assess the intensity or effort put into job search. For example, an individual is asked to rate his or her frequency in carrying out an array of job search behaviors over a specific period of time.

A trend in the job search literature is to consider the nature of job search behavior. A particularly useful and well-accepted approach is distinguishing between preparatory and active job search behaviors. *Preparatory search behavior* involves assessing whether desirable alternatives exist and would include such behaviors as talking to friends or relatives about possible employment leads or reading job postings in a newspaper, in a journal, through a professional association, or on the Internet. *Active search behavior* is the attempt to determine the actual availability of those alternatives to the individual and includes behaviors such as sending one's résumé to a prospective employer or contacting a search firm, employment agency, or state employment service. Research has generally found that preparatory and active search

are distinct dimensions with different antecedents and outcomes. For example, preparatory job search tends to precede active job search, and active search is a stronger and more proximal predictor of job choice decisions.

THE JOB SEARCH CONTEXT

People search for employment opportunities in a variety of contexts, including job market entry (or reentry) following a period of full-time education, unemployment because of job loss, or seeking alternative employment while currently employed. The job search determinants, processes, and outcomes are often quite different depending on the specific context of focus. That is, how a recent college graduate goes about searching for a job, what factors drive his or her search, and the relevant search outcomes are typically distinct from individuals who have been laid off from a job or from those seeking alternative employment opportunities while already holding a job. As an example, an important outcome for unemployed individuals (whether unemployed because of job loss or following full-time education) is simply becoming employed. Yet employed job seekers may not necessarily be searching to obtain a job, but may actually have other motives (e.g., to establish networks, to demonstrate marketability to current employer) driving their job search activity.

PREDICTORS OF JOB SEARCH

Although the relevant predictors of job search can vary across contexts and samples, job search predictors can be classified broadly as person attributes, situation attributes, and market attributes. *Person attributes* reflect relatively enduring characteristics about an individual. This would include personality traits (e.g., self-efficacy, Big Five personality factors) and biographical (e.g., gender, race) and human capital (e.g., ability, experience, education level) factors. Recent research suggests that individuals who are more extraverted, conscientious, and open to experience engage in more job search. Self-esteem and self-efficacy are also strong predictors of more job search. The strongest biographical/human capital antecedents are education level (positively related) and job tenure (negatively related).

Situational attributes change with particular employment and personal circumstances or may

reflect individual reactions to and perceptions about a particular situation. In regard to predicting job search activity, these would include motive-related antecedents such as financial need and commitment to employment, as well as social support variables. For employed individuals, characteristics of the current employment situation play a significant role in predicting search activity as well as other retention-related constructs (e.g., intent to quit, voluntary turnover). Examples include general work attitudes such as job satisfaction and organizational commitment; objective factors including pay and benefits, type of work, and working conditions; and perceptions of and reactions to these objective variables (e.g., perceived fairness of pay, feelings toward one's supervisor and/or the work environment, and person-organization fit).

Finally, market attributes affect the relative supply of and demand for labor and thus can influence job search. Relevant factors include alternative opportunities, cost-benefit decisions, and the industry or the type of job sought. Existing research on the effect of perceived alternatives on job search activity is somewhat equivocal and deserves further discussion. Specifically, it has been argued that those perceiving more alternatives should have greater confidence in their ability to find a new job and thus search more. Yet those with greater marketability may require less search either to locate suitable alternatives or to acquire needed information. As noted, empirical research findings are mixed, and the nature of the effect is likely to depend on the job search context of focus.

JOB SEARCH OUTCOMES

The general notion of job search success is often of interest as a dependent variable. For new job market entrants as well as unemployed individuals, simply whether one is employed (i.e., employment status) following job search is particularly relevant. Other criteria of job search success include number of interviews and/or number of offers following job search, with the assumption often being that more is better. That is, more interviews and/or more offers are generally seen as indicating job search success. Some research has questioned this perspective, recognizing, for example, that efficiency in the job search process may be more desirable. As an example, an individual who has 10 interviews leading to 2 job offers is not necessarily more successful than an individual who

interviews with one company and receives a job offer, particularly if the latter individual receives an offer from his or her employer of choice.

Another measure of job search success is the quality of the offer(s) received or job ultimately accepted. The challenge researchers face in assessing the quality of employment is that there are many job attributes that may reflect the quality of a job (e.g., pay, location, work culture, advancement opportunity). The assessment, as well as importance of the various attributes, is often in the eye of the beholder.

The duration of job search is another potentially relevant outcome variable. In this case, the focus is generally on time (e.g., weeks) from the onset of search (e.g., loss of job) to employment, with shorter duration indicating higher job search success. Duration of job search is particularly relevant for unemployed individuals, whether unemployed because of job loss or following full-time education. The longer it takes to find a job, the more likely an individual may be to drop out of the labor market, which has important societal and policy implications.

The basic finding in the job search literature is that job search intensity increases one's probability of and speed in finding employment, although not necessarily the quality of employment. In terms of different job search sources, research suggests that job seekers are more likely to use and find employment through informal sources (e.g., friends, acquaintances) than through more formal methods (e.g., employment agencies). Length of service in a job, another indicator of job search success, also tends to be higher when informal job search sources are used. More research attention on the use and consequences of various job search sources is certainly warranted, particularly with the growing reliance on the Internet for job search purposes.

In the context of employed individuals, job search is often seen as a precursor to voluntary turnover. Indeed, the traditional turnover model assumes that employee dissatisfaction leads to withdrawal cognitions, then a search for alternatives, followed by an evaluation of alternatives, and ultimately a decision to quit or stay. Thus, search is seen as instrumental in leaving an organization for alternative employment. Consistent with this model, job search activity is one of the strongest predictors of employee turnover, although job search tends to explain a modest 4% to 6% of the variance in turnover. Of course, not everyone who desires to leave and searches for an alternative

job can find available opportunities that are necessarily more attractive than the current employment situation, and some individuals quit without searching at all. Both of these factors provide explanations for the moderate (albeit significant) relationship between job search and employee turnover. Yet, as indicated previously, research has begun to recognize that individuals engage in job search for reasons other than to leave the current employment situation. Considering the motives behind an individual's job search, beyond the assumption that individuals search to leave the current employer for a new job, will help contribute to better understanding to the consequences of employed individuals' job search activity. Interestingly, there has been little research on how job search affects such things as subsequent work attitudes, social relations (with supervisors or coworkers), and work motivation and performance outcomes, particularly when an employee searches but does not end up leaving the current employer.

SUMMARY

At any given time, many people are searching for employment opportunities. The nature of their behavior and the context in which they search can be quite varied. Yet whether search is viewed as part of the job evaluation and choice process or within the framework of employee withdrawal and turnover, the objective of job search is typically to investigate and generate job alternatives. Whether an individual is successful in that respect, and the resultant outcomes, is a function of the person, the situation, and the larger labor market.

JOB SECURITY/INSECURITY

Job security and job insecurity can be viewed as opposite sides of the same coin. Simply defined, *job security* is assured continuity of one's job, and *job insecurity* is the uncertainty that one's job will continue. The term *job insecurity*, rather than *job security*, is more commonly used in the literature.

A more comprehensive definition of *job insecurity* is powerlessness to assure desired continuity of one's job or job components when either the job or its components is threatened. The term *job insecurity* can refer not only to the potential loss of the job itself, but also to the threatened loss of key components of the job, such as supervisory activities or pay. The fuller definition of *job insecurity* is derived from underlying themes of anticipation, risk, and powerlessness. Job insecurity is focused on anticipation of a possible future event, namely job loss. The future focus of job insecurity suggests that employees faced with job insecurity consider the consequences that job loss would bring, such as financial strain. Job insecurity also involves risk that job loss or loss of job components would result in a corresponding loss of something of value. The loss might be simply monetary, or it could be intangible, such as loss of status provided by the job. Job insecurity definitions also often incorporate the concept of powerlessness to reduce job insecurity.

TAXONOMY OF JOB INSECURITY

Job insecurity can be further classified as subjective or objective; cognitive or affective; and global or multifaceted.

Subjective or Objective

In research, job insecurity primarily has been conceptualized as subjective in nature. This implies that individual psychological interpretations of job insecurity vary and that these interpretations play a crucial role in individual responses to job insecurity. Objective job insecurity, alternatively, is the actual degree to which the future of one's job is uncertain. If individuals are unaware that their jobs are at risk or refuse to believe that their jobs are at risk, then they might not perceive job insecurity even if objective job insecurity exists. Indeed, the relatively weak relationship between objective and subjective job insecurity indicates that the existence of one is not a prerequisite for the existence of the other.

Cognitive or Affective

Belief that one's job will be lost is the cognitive aspect of job insecurity. In contrast, the feelings that one has about the possible job loss constitute the affective component of job insecurity. A distinction can be made between the perceived likelihood of job loss and a concern about job loss. Workers can believe that job loss is likely without feeling concerned. This lack of concern might hold true for those who are ready to leave the workforce, such as workers close to retirement age and those with other job offers. In contrast, workers can feel concerned about potential job loss even if they believe that their jobs are secure. Concern about job insecurity might outweigh belief that one's job is secure for individuals who have great financial responsibilities or those who feel that few job options are open to them.

Global or Multifaceted

Global job insecurity focuses on the potential loss of the job in its entirety. It is more commonly studied than a multifaceted approach to job insecurity, which encompasses potential loss of both components of the job as well as the entire job. There is some debate on whether loss of job components is as important as loss of the job itself. Loss of job components might not be as severe as loss of the job itself, because even when components are lost, the individual still retains organizational membership. The contrasting argument states that reactions to threatened loss of at least

certain job components are substantively similar to threatened loss of the job itself.

CONSEQUENCES OF JOB SECURITY/INSECURITY

Job insecurity has strong psychological implications and is considered one of the most stressful aspects of the work situation. The role that employment plays in our society turns the prospect of job loss into a threat. Job insecurity not only jeopardizes individual economic security; it can also threaten intangible social needs that are often met by work, such as a sense of status or identity.

Outcomes associated with job insecurity can be grouped by type and focus of reaction. Types of reactions include immediate and long-term consequences, and focus of reactions is either individual or organizational.

Job and Organizational Attitudes

Attitudinal reactions to changes in job security tend to manifest themselves quickly. Those consequences of job insecurity that are classified as job attitudes are both immediately felt and focused on the individual rather than the organization. Job satisfaction and job involvement are included in this group. As job insecurity increases, job satisfaction and job involvement decrease.

Like job attitudes, organizational attitudes are quickly affected by a change in job security. The focus, however, is on attitudes toward the organization as opposed to intrapersonal dynamics. Job insecurity has been correlated with decreased affective organizational commitment, increased continuance commitment, decreased trust in the organization, and decreased perceived organizational support.

Well-Being

Some outcomes of job insecurity, such as individual physical or psychological well-being, manifest themselves more slowly. Physical health issues related to job insecurity include somatic complaints such as fatigue and pain and heart-related problems such as elevated blood pressure and ischemic heart disease. Job insecurity is associated with general psychological distress as well as with decrements in specific

forms of psychological well-being, such as strain and burnout, depression, and anxiety.

Work-Related Behavior

Work-related behaviors can be classified as a long-term consequence of job insecurity, because the effects of job insecurity on work-related behaviors are not immediately apparent. Rather than having an internal focus, work-related behaviors are focused external to the individual, on the organization. Although some studies have found an inverse relationship between job insecurity and performance, others have not. This lack of relationship was supported by a recent meta-analysis. Closely related to performance, work effort has been found to have a curvilinear relationship with job insecurity, with work effort being highest at moderate levels of job insecurity. Two other work-related behaviors, intention to leave and job-seeking behavior, also are positively associated with increased job insecurity.

ANTECEDENTS AND MODERATORS

Like any predictor, job security/insecurity is not without its antecedents and moderators.

Antecedents of Job Security/Insecurity

Job security/insecurity is generally examined as a predictor. As a result, less attention has been given to antecedents of job insecurity. The relationship between gender and job insecurity suggests that men and women do not view job insecurity in the same way, and they react to job insecurity differently. Women appear to perceive greater job insecurity and to be more concerned about job insecurity than men. Personality also appears to play a role in determining job insecurity. Positive personality attributes lessen job insecurity, and negative attributes, such as neuroticism, increase perceptions of job insecurity.

Experience with organizational change in the form of downsizing or merger and acquisition relates to greater job insecurity. Regardless of whether the change is in the future, present, or past, job insecurity appears to be affected. Employees who anticipate a merger or acquisition, along with those in organizations currently downsizing, report greater job insecurity. Individuals who have personal experience with layoffs subsequently report lower job security.

Violations of psychological contract, such as a failure to meet expectations of career advancement, also are associated with increased job insecurity. These findings hold even though expectations of job security are no longer considered to be part of a relational psychological contract.

Moderators of Job Security/Insecurity

Based on the results of a recent meta-analysis of job insecurity, moderators play a substantive role in explaining the relationship between job insecurity and its outcomes. Social support has been found to moderate the relationship between job insecurity and job satisfaction and between job insecurity and noncompliant job behaviors. Social support also moderates the relationship between job insecurity and job-seeking behavior. As well as directly relating to job insecurity, job involvement acts as a moderator of the relationship between job insecurity and job satisfaction and the relationship of job insecurity with intention to leave. Occupational status moderates the role between job insecurity and two of its outcomes. Manual workers have a stronger relationship between job insecurity and performance and between job insecurity and intention to leave than do nonmanual workers. Additionally, the method used to measure job security/insecurity can affect its relationship with its outcomes. Single-item job insecurity measures are associated with weaker relationships between job insecurity and job satisfaction, trust, and performance.

MEASURING JOB SECURITY/INSECURITY

Assessing job security/insecurity via self-report tends to be the norm. Likewise, subjective job security/insecurity is more commonly assessed than is objective job insecurity.

Measuring Objective Job Insecurity

Regardless of the measurement method chosen, quantifying objective job insecurity can be difficult. On an individual basis, the terms of the employment contract can be examined for verbiage concerning contract length. Within the organization, managers can rate the security of a particular job. Industry-wide ratings of objective job insecurity can be made by determining the growth rate of an industry. The assumption is that jobs at organizations in a growth industry are secure, whereas those in a declining

industry are insecure. Alternatively, individuals can report whether certain events, such as downsizing, have occurred in their organizations. These self-report responses indicate the occurrence of the event rather than the incumbent's interpretation of said event.

Measuring Subjective Job Insecurity

No single measure is commonly considered the best measure of subjective job insecurity. Current measures vary from a single self-report global item to lengthy self-report multidimensional measures. The single item typically asks, "How secure (or insecure) is your job?" On the other end of the spectrum, a 52-item measure based on Leonard Greenhalgh and Zehava Rosenblatt's conceptualization of job insecurity involves determining the importance and likelihood of loss for both the job and key job components, along with assessing the perceived powerlessness to resist the threatened loss. Most measures fall in the middle in both length and complexity. Typical measures assess global subjective job insecurity in 3 to 5 items. Measures that also assess potential loss of job components tend to be two-dimensional, with one asking about security of the job itself and the second asking about security of key job components. A pair of newer measures also makes the distinction between cognitive and affective subjective job insecurity.

JOB SHARING

Job sharing describes the sharing of one full-time job by two part-time employees, requiring interaction and collaboration between two part-time employees in completing work goals. Generally, pay and benefits are distributed equally between the part-time workers involved in job sharing. Objectives of job sharing include improved management of work and family responsibilities, better retention of highly qualified employees, leveraging the skills and experiences of two part-time instead of one full-time employee, and higher flexibility for the employees involved.

HISTORY AND PREVALENCE OF JOB SHARING

Job sharing was first developed in the 1960s to provide employees with more part-time employment opportunities. In contrast to traditional part-time employment, job sharing was designed to allow the sharing of professional jobs that entail higher levels of organizational responsibility than traditional part-time jobs. Initially, job sharing was limited to government jobs, but it spread to the private sector in the late 1970s and 1980s. Despite the advantages of job sharing, it is not as common as other part-time working arrangements—in the 1990s, between 22% and 47% of organizations reported offering job sharing to their employees as one part-time employment option. The prevalence of job sharing differs based on industry; job sharing is more common in the health care and government sectors than in other industries. Today, job sharing is accomplished using different scheduling techniques. Some jobs are shared so that each of the two employees covers a whole week and then has a week off. Other job shares involve the splitting of daily responsibilities. For example, one employee

may work during the morning and the other job sharer, in the afternoon. Daily rotations between the two employees are another form of job sharing; one employee may cover Mondays, Wednesdays, and part of Fridays, and the other may cover Tuesdays, Thursdays, and the other part of Fridays. Although both men and women are involved in job sharing, women with young children are overrepresented among job sharers.

RESEARCH FINDINGS ON COSTS AND BENEFITS OF JOB SHARING FOR EMPLOYERS AND EMPLOYEES

Employers

Organizations interested in implementing job sharing face various costs and benefits of program implementation. Several costs have been found to be consequences of the implementation of job-sharing programs: Job sharing has been identified to relate to increased training costs—in job-sharing situations, two employees, instead of one, have to be trained to fill a job. Usually, both employees receive benefits, which can lead to increased benefits costs if services such as health insurance have to be provided to more than one employee. Costs for personnel administration also rise if job sharing is in place. Again, this greater cost is caused by pay and benefits needing to be administered to two employees instead of one. Further costs can arise if the job-sharing employees communicate ineffectively. Miscommunication may lead to duplicated work or wasted time as employees try to establish what work has been finished. Conversely, employers can benefit substantially from having job-sharing programs: If two employees are trained to fill the same position, one can fill in if the other is absent. Thus, employee illness and vacation times are less disruptive if job-sharing programs are in place than if a single employee fills the same position. Further organizational benefits of job sharing include enhanced employee retention and enhanced productivity through potentially complementary employee strengths, abilities, and skills directed toward work objectives. From a recruitment perspective, job sharing can also lead to a competitive advantage for an organization—a position advertised as being available on a full-time or job-sharing basis exploits both full-time and part-time labor markets.

Employees

For employees, job sharing has been found to provide opportunities for successful management of work and personal responsibilities. Employees generally value the availability of job-sharing opportunities. Such opportunities help employees balance work and family responsibilities, raise children, obtain additional education in their free time, or develop additional professional interests during later stages of their career. Particularly those with young children value employers who provide part-time working arrangements such as job sharing. Studies conducted in the health care sector show job sharing to relate to higher satisfaction and physical health status than flextime and other part-time or full-time working arrangements. Also, longitudinal studies of job sharers demonstrate that although initially the well-being of those in job-sharing arrangements did not surpass that of other part-time employees, long-term effects were more positive. Job sharing is not without negative outcomes, however. Employees engaged in job-sharing arrangements can also incur costs: Research has found job sharers to be more likely to quit their jobs than full-time employees if their psychological contracts are violated. Although job-sharing employees experience more advancement opportunities than traditional part-time employees, they still have fewer opportunities than full-time employees. In many organizations, an individual's decision to take a job-sharing position is interpreted as low commitment to career and organization, leading to reduced opportunities for advancement and training. In addition, employees involved in job sharing experienced lower levels of sex discrimination than other part-time employees, but still higher levels of sex discrimination than full-time employees. Some job sharers have reported feeling they had to accomplish a full-time job on a part-time schedule, making job sharing a demanding experience. Other negative consequences of job sharing occur if the two employees sharing one full-time job communicate ineffectively, as previously mentioned, or define their respective roles insufficiently. Unions generally view job sharing favorably, because benefits and job security of job-sharing employees are usually better than those received by other part-time employees. Last, supervisors with no previous exposure to job sharing were found to react cautiously toward the prospect of having employees involved in

job sharing but evaluated job sharing more positively if they had previous exposure.

JOB TYPOLOGIES

A frequent need in organizations and organizational research is to classify individual positions or jobs into groups, with each group internally homogeneous in terms of a profile of relevant psychological characteristics (e.g., abilities) and situational characteristics (e.g., job requirements) and at the same time externally distinct from all other groups. A job typology is either an established framework—and several major ones will be reviewed here—or it is derived through analytic procedures applied to data at the individual and/or job level, but in either case job typologies contain groups of jobs that, to a greater or lesser extent, adhere to the aforementioned principle of internal

consistency and external distinctiveness. This classification process is similar in spirit to factor analysis, in the sense that it results in a small yet sensible number of groups to simplify and amplify relevant similarities and differences. Rather than serving as an end in itself, however, job classification is a tool that can assist in a whole host of personnel-related functions, such as appraising employee job performance, validating employee selection tests, evaluating jobs, planning career paths, and counseling individuals seeking vocational guidance. There are many practical benefits of grouping jobs effectively. For example, rather than having to develop distinct measures to assess employee performance for each individual job in an organization, job grouping can justify developing measures for a smaller set of job groups. Thus, grouping transforms a potentially cumbersome, costly, and time-consuming task into a more manageable, less expensive, and less time-consuming task that is, one hopes, just as useful. Of course, the practical benefit of reducing the total number of jobs to a manageable and appropriate number of job families depends on theoretical notions of generalizability, first that jobs can be aggregated into job families on characteristics that are relevant across jobs (versus those unique to jobs and job positions), and second that whatever unique information about jobs might be sacrificed through grouping jobs does not adversely affect the purposes to which the resulting job groups are put. Of course, unique job information can serve to supplement the organizing scheme provided by a job taxonomy.

OCCUPATIONAL INFORMATION NETWORK (O*NET) AND THE STANDARD OCCUPATIONAL CLASSIFICATION (SOC) SYSTEM

Established in 1998, the Occupational Information Network (O*NET) is the Department of Labor’s computerized replacement to the longstanding *Dictionary of Occupational Titles* (DOT). The O*NET is intended to be a comprehensive and flexible taxonomic system to categorize jobs in the United States along a multitude of dimensions for the purposes of work-related activities such as employment testing, training, compensation, recruitment, and vocational education and counseling. Rather than using the data–people–things framework the DOT relied on for classifying jobs, the O*NET database is organized

around a framework called the *content model*, which comprises six broad areas, the first three being worker-oriented and the last three being job-oriented:

- Worker requirements (e.g., basic skills, cross-functional skills, education)
- Worker characteristics (e.g., abilities, interests, work styles)
- Experience requirements (e.g., training, experience, licensing)
- Occupation requirements (e.g., work content, organizational context)
- Occupation-specific information (e.g., occupation-specific knowledge, skills, tasks, and tools and equipment)
- Occupation characteristics (e.g., labor market information, wages)

Ratings of the level and importance of worker and job characteristics from these six major areas are collected from workers and supervisors across jobs on a continual basis, with most data being collected on relevant cross-job characteristics, versus the task-specific and worker-specific emphases found in the DOT. Research investigating the reliability, interrater agreement, factor structure, and validity of the data is ongoing. The O*NET system uses the Standard Occupational Classification System (SOC), which is the standard toward which all U.S. government agencies are moving.

GUIDE FOR OCCUPATIONAL EXPLORATION

The *Guide for Occupational Exploration* (GOE), developed by the U.S. Employment Service in 1979, is an occupational typology that arises from a rational-empirical approach to measuring occupational interests, and it is still in use for career exploration and vocational counseling purposes. The interest framework contains 12 factors that can be grouped by pairs into the Holland RIASEC framework of interests (realistic, investigative, artistic, social, enterprising, and conventional interests). Jobs within this framework incorporate most if not all jobs within the O*NET; they subdivide into 66 groups when groups are further differentiated by educational, physical, task-based, and situational factors; and the groups fractionate further into 348 subgroups. For the purpose of career exploration, the 66-group level of categorization is the main emphasis in the GOE, where

both ability profiles (e.g., from the General Aptitude Test Battery, or GATB) and occupational interest profiles (e.g., from Holland RIASEC codes) can be assigned to jobs. This job taxonomy is perhaps more theoretically focused than the O*NET, although the O*NET contains a crosswalk of codes to structure its occupational data into the GOE framework. The Occupational Aptitude Patterns (OAP) Map complements the job groups of the GOE by arraying them into four major categories based on ability profile requirements (physical, bureaucratic, social and economic, and artistic) and into five levels of general cognitive ability requirements. Both abilities and vocational interests are found to fit within the OAP Map. Other taxonomies also apply theoretical interest and ability structures to occupational structures. The American College Testing (ACT) Program's World-of-Work Map (which makes use of the Holland RIASEC structure) and the Minnesota Occupational Classification System III (MOCS-III, which integrates interests, ability, and motivational characteristics in matching individuals and jobs) are two major exemplars for the purpose of matching individuals to jobs in vocational counseling.

OCCUPATIONAL OUTLOOK HANDBOOK

The *Occupational Outlook Handbook* (OOH), first published in 1948 by the U.S. Bureau of Labor Statistics (BLS), is updated yearly and contains a wide range of occupational information, with jobs classified by SOC codes (similar to O*NET) and SOC codes comprising approximately 270 occupations that are grouped into 10 broad clusters: management, professional and related occupations, service, sales, administrative support, farming and related occupations, construction, installation and related occupations, production, and transportation, with additional discussion about careers in the U.S. armed forces. Each occupation contains seven major sections describing it:

- Nature of the work (e.g., job duties; level of responsibility by industry and by job type)
- Working conditions (e.g., hours worked; physical environment; level of safety; amount of travel required)
- Employment, training, other qualifications, and advancement (e.g., type and length of training; required degree, license, or certification; continuing education needs)

- Job outlook (e.g., projected growth or decline; number of jobs; level of competition for jobs)
- Earnings (e.g., how workers tend to be compensated, whether by salary, commission, or bonuses and tips; how income varies by experience and geographic region; typical benefits)
- Related occupations
- Sources of additional information (e.g., referrals to other agencies or organizations, publications, and Web sites)

OCCUPATIONAL EMPLOYMENT STATISTICS

Occupational Employment Statistics (OES), also produced by the BLS, is a primary source for those seeking detailed information on earnings, as the OES collects data on employment and wages semiannually from 200,000 establishments, sampling across approximately 800 full-time and part-time occupations (excluding farm-related) that represent the U.S. workforce. Occupations are organized into 22 groups by SOC code. Wages and employment levels are provided at the national, state, and metropolitan area levels; they are provided by hourly wage and annual wage, as well. (Data are accessible for free at <http://www.bls.gov>.)

NORTH AMERICAN INDUSTRY CLASSIFICATION SYSTEM

In addition to the OES and OOH, in 1997 the BLS created the North American Industry Classification System (NAICS), as the updated replacement of the Standard Industrial Classification (SIC) system. As the name implies, NAICS is the product of a joint cooperation between the United States, Canada, and Mexico (the trading countries of NAFTA, the North American Free Trade Agreement), and occupations are grouped by industry in a manner that reflects similarities in production processes or *how* things are produced, not in *what* is produced. Multiple U.S. government agencies collect and organize data on employment, wages, turnover, and occupational safety and health under the NAICS system; the system is separate from the SOC but shows clear and direct linkages. Linkages among several classification systems can be obtained online from the National Crosswalk Service Center.

CONCLUSION

Job taxonomies such as O*NET, the GOE, the OOH, and NAICS allow a number of important psychological and situational factors to influence the resulting job groups—both explicitly and implicitly. Researchers and practitioners in areas such as personnel selection and training, wage compensation, and vocational counseling may want to pay close attention to their choice of a job taxonomy—specifically the type and the narrowness or breadth of job groups—because the choice of taxonomy may have important effects on the decisions that result from them.

JUDGMENT AND DECISION-MAKING PROCESS

Judgment and decision making (JDM) refers to an interdisciplinary area of research that seeks to determine how people make judgments and choices. The field considers perspectives from psychology, sociology, and economics; JDM researchers are found in psychology, management, economics, and marketing departments, as well as in schools of medicine, engineering, and public health. As this volume is concentrated on industrial/organizational psychology, we adopt a mostly descriptive (i.e., psychological) perspective in discussing this topic. Psychologists have been concerned mostly with how people actually make decisions, whereas researchers from other areas (e.g., economics) have been concerned mostly with the rules that people should follow when making choices.

EXPECTED UTILITY THEORIES

In general, decisions can be categorized depending on whether the outcomes of the available options are known for sure (decisions under certainty) or whether the outcomes are uncertain and occur with known or uncertain probabilities (decisions under uncertainty). Most research has focused on decisions under uncertainty, because such decisions are more common. Traditional theories of choice under uncertainty, such as subjective expected utility theory (SEUT), posit that choices are derived from only two parameters: (a) the subjective value, or utility, of an option's outcomes and (b) the estimated probability of the outcomes. By multiplying the utilities with the associated probabilities and summing over all consequences, an expected utility is calculated. The option with the highest expected utility is then chosen.

DECISION ANALYSIS

This rational model of decision making has been used as a guide to study actual decision behavior

and as a prescription to help individuals make better decisions. Multiattribute utility theory (MAUT) is a type of expected utility theory that has been especially influential in decision analysts' attempts to improve organizational and individual decision making. Using MAUT, decision makers carefully analyze each option for its important attributes. For example, a job could be characterized by attributes such as salary, chances for promotion, and location. Decision weights are assigned to attributes according to their importance to the decision maker. Then, each available option is assessed for its expected value on all attributes. The values are then multiplied by the decision weights and summed, and the option with the highest value is selected.

Decision analysts have also developed various decision aids to help individuals and organizations make better decisions. Many of these aids rely heavily on modern information and communication technology, such as management information systems, expert systems, and artificial intelligence. Because few empirical evaluations of the various decision aids have been undertaken, claims about their effectiveness are mostly based more on logical argument than on research and should be considered speculative.

PROSPECT THEORY

Theories of expected utility, such as SEUT, impress through their simplicity, generality, and rational appeal. However, they also place heavy demands on decision makers' knowledge and cognitive abilities and neglect important aspects of the decision process, such as the search and interpretation of information. Under the *heuristics and biases* approach, JDM researchers have explored various ways in which decision makers deviate from rationality. The most important result of this research program is prospect theory.

Prospect theory (PT) was developed as a descriptive theory of decision making. Prospect theory uses a multiplicative model similar to the one used by expected utility theories. However, instead of utilities and probabilities, PT proposes that decision makers use certain value functions and decision weight functions. The decision weight function differs from a probability function in that low probabilities are overweighted and high probabilities are underweighted. The value function also differs from a typical utility function. Specifically, PT assumes that values are defined relative to a reference point (or the status quo). Further, PT posits that the value function is

steeper in the domain of losses (below the reference point) than gains. Finally, the value function is concave above, and convex below, the reference point. This implies that decision makers are risk-averse in the gain domain but risk-seeking in the domain of losses.

Emotions and Motivation in Decision Making

A limitation of PT is the heavy emphasis on cognitive and psychophysical aspects of decision making. Common experience suggests that making choices can involve intense emotions. This is reflected in research on regret aversion. When making decisions, people often worry about the possibility of experiencing regret as a result of choosing an inferior option. Recent research suggests that such worries can even lead to better decision making by motivating people to engage in more vigilant information search and deliberation before making a choice. Other research suggests that positive affect can have beneficial effects on decision making—for example, by increasing creativity.

A related branch of decision-making research deals with flawed decision behavior when the optimal choice is readily apparent. In such situations, the decision maker is actually *motivated* to choose the option that is destructive in the long term. Decision-making researchers have identified this as an intrapersonal conflict, between what one wants to do and what one knows one should do. There are many nonwork examples of such decisions, such as when students elect to attend a party rather than study for an upcoming exam, or when cigarette smokers attempting to quit, despite their best intentions, accept a cigarette offered to them at a party. Such decisions are considered nonoptimal when, considered retrospectively, they lead to regret because they are inconsistent with decision makers' long-term goals. There are many explanations for why individuals give in to their "want selves," such as dispositional self-control and allowing themselves to reason through unwise promises (e.g., running up one's credit card today while promising to stop next month).

Another explanation for these effects is *time discounting*. For example, consider when an honest employee has decided to confront a needy coworker who has been stealing from the company to make ends meet and provide for his family. The employee knows that it is in the best interest of the organization in the long term to confront the employee and ask him to curtail his behavior. However, these plans are

destroyed when the dishonest but very likable coworker walks into the break room and the topic discussed is not the coworker's theft, but mundane, friendly topics such as work and the weather. In this case, the long-term goals of unit performance and management trust are devalued relative to the more immediate feelings of comfort and positive emotional reactions by the coworker. Over time, such decisions can have negative effects on individual and organizational performance.

INDIVIDUAL DIFFERENCES AND DECISION MAKING

As compared with industrial/organizational (I/O) psychology's long-standing interest in individual differences, the interests of JDM researchers so far have had less to do with individual differences in decision making and their relation to decision quality and outcomes. An exception to this is the *decision-making styles scales*, which were developed to measure the degree to which decision makers report intuitive, dependent, rational, avoidant, and impulsive decision making. One recent study adapted the rational and intuitive items to job search and found that self-reported rational and intuitive strategies were related to job satisfaction and satisfaction with the job search process. Given that decision making is an important dimension of most managerial jobs, understanding the relation between decision making styles and managerial performance could be an important addition to the employee selection literature. Organizations might consider adding measures of decision making styles to selection batteries or adding decision-making style training for managers.

FAIRNESS IN DECISION MAKING

Most decisions, especially in organizations, affect not only oneself, but others, as well. This raises questions of how decision outcomes should be distributed across parties. Research on *organizational justice* is concerned with the characteristics of decision processes and distributions of decision outcomes that lead to higher or lower levels of perceived fairness. Because there are entries in this volume that describe the research on organizational justice perceptions extensively, here we concentrate only on the tension between what is rational and what is perceived as fair. From the standpoint of economics, decisions that maximize utility or profit should be preferred by

decision makers. However, research shows that often individuals will sacrifice personal rewards to punish (a) someone who has acted unfairly toward them or (b) an individual who has wronged someone else when they have no relationship with either party. This speaks against pure self-interest and value maximization.

Consider a so-called *ultimatum game* in which someone is willing to split \$100 between two parties provided that they can agree on how to split the money. One person is to make a decision on how to distribute the money, whereas the other person only has to decide on whether to accept the decision, or no money is distributed. Assume one party decides to take \$98 of the money and give \$2 to the other party. A value-maximizing decision maker should accept this decision. However, the majority of people playing this game reject this unfair distribution. Although such ultimatum games clearly have workplace applications, virtually none of this research has made it out of the laboratory and into workplace settings. We believe that self-sacrificial decision making to punish perceived unfairness in the workplace is an area for potentially interesting future research.

APPLICATIONS TO JOB CHOICE AND EMPLOYEE SELECTION

Perhaps the areas in which JDM has contributed the most to I/O psychology are in job choice and employee selection. In the area of job choice, perhaps the largest area of cross-fertilization between JDM and I/O psychology is the application of the policy-capturing (PC) methodology to study job attribute preferences. Briefly, with the PC methodology, participants rate job-choice scenarios that differ on multiple job attributes. Participants provide some indication of organizational attractiveness on a Likert-type scale; then, using multiple regression, the researcher can determine for each individual the unique influence of each attribute on attractiveness ratings. Although the PC methodology also suffers from some limitations, it has allowed us to draw some conclusions about which job attributes are most important. These include opportunities for advancement, social status and prestige, responsibility, opportunities to use one's skills, challenging work, opportunities to be creative, and high salary.

In both employee selection and job choice contexts, some I/O researchers have sought to determine whether phenomena observed in other decision-making contexts (e.g., consumer purchases) are also

observed when the choice is among hypothetical job candidates or hypothetical job offers. Phenomena studied in selection contexts include order effects, attribute-range effects (i.e., the effects of high versus low variance on salary in job choice), attribute-salience effects (i.e., the effect of unique favorable attributes versus unique unfavorable attributes in options that are similar in overall attractiveness), and decoy effects (i.e., when the manipulation of the characteristics of an inferior option causes preference to shift between two superior options). In general, the published studies indicate that these effects are generalizable to job choice and employee selection contexts; however, when efforts have been made to make the decision context more similar to real-world decision making (e.g., when attributes are presented in text form or without numerical values), the effects tend to be weaker.

CONCLUSION

The fields of decision making and I/O psychology have much to offer to each other. However, I/O researchers have not to this point taken full advantage of JDM research. Many decision-making phenomena observed in the laboratory are potentially relevant to organizations but have not been studied in organizational contexts. Likewise, JDM researchers could learn from I/O psychology's sophistication in such areas as field methodology and test construction. More communication between JDM and I/O researchers in the future can benefit both fields.

JUDGMENT AND DECISION-MAKING PROCESS: ADVICE GIVING AND TAKING

When faced with work-related decisions, job seekers, employees, managers, and even the highest ranked corporate officers all have one thing in common: They are likely to ask other people for advice. For example, human resources managers might ask for their colleagues' opinions before hiring one of several job candidates. Thus, individuals seldom make work-related decisions without another person's advice.

A program of research launched by Janet A. Sniezek specifically studies the giving and taking of advice. This research is best known under the label of judge–advisor systems (JAS), although complementary research has also been conducted under the rubric of hierarchical decision-making teams. The central tenet of the JAS research is the recognition that, although decision makers are likely to be influenced by others during the decision-making process, the responsibility for making the final decision is solely the decision makers'. This principle is important because it sets the research on advice giving and taking apart from the more general research on group decision making. In the latter case, all group members are presumed to have the same status within the group, and they all share the same responsibility for the final decision. This is not the case in JAS research.

JUDGE–ADVISOR SYSTEM TERMINOLOGY

Judge–advisor system research has traditionally employed the term *judge* to refer to the decision maker—that is, the recipient of advice. The *advisor* is, as the term implies, the provider of advice. The JAS, then, refers to an entity composed of the judge and one or more advisors who engage in a decision-making task.

In JAS research, advice given to decision makers often takes the form of a recommendation for a specific course of action (e.g., “you should do X,” or “you should choose the first option”). However, there is growing evidence that advising interactions contain more than the provision of a specific recommendation. In fact, advice also includes behaviors such as recommending the decision maker *not* to choose one of the current alternatives, providing new information about one or more of the decision maker's current alternatives, or suggesting a new alternative that the decision maker had not initially thought about. In addition, advice can take the form of helping decision makers structure and organize the decision-making process. For example, advisors can suggest making a list of pros and cons for each potential alternative. Finally, advisors can provide socioemotional support, such as when they empathize with the decision maker.

Although the term *advice* refers to a collection of behaviors, most of the JAS research conducted to date involves the exchange of advice defined as a recommendation for a specific course of action. This research can be divided into two broad categories: advice taking and advice giving. Whereas the latter stream of research takes the perspective of the advisor, the former takes the perspective of the decision maker (or the judge).

ADVICE TAKING

One of the main questions asked by researchers interested in advice taking is what happens when decision makers receive another person's recommendation. A central finding of this research is that of egocentric advice discounting. Although advice generally helps decision-making accuracy, decision makers' postadvice opinion is influenced to a greater extent by their own opinions than by their advisors' recommendations. In other words, decision makers tend to disregard advisors' recommendations relative to their own preadvice opinions. Egocentric advice

discounting is a robust phenomenon. However, some conditions diminish decision makers' propensities to overweight their opinions relative to the advisor's recommendation (although some discounting typically still occurs).

First, advice is less likely to be egocentrically discounted, as well as less likely to be perceived as intrusive, when decision makers explicitly ask for advice as opposed to when advisors offer unsolicited advice. Egocentric advice discounting is also less likely to occur if advisors are more experienced than decision makers are, either in terms of task-related expertise (e.g., an expert advisor giving advice to a relatively novice decision maker) or in terms of personal characteristics that denote experience (e.g., older or more educated advisors). Relatedly, less experienced decision makers utilize advice to a greater extent than more experienced decision makers do, and decision makers utilize advice to a greater extent on complex than on simple tasks. Furthermore, decision makers are more likely to utilize advice when they and their advisors receive monetary rewards, especially when decision makers can distribute financial incentives prior to receiving their advisors' recommendations. This closely parallels situations in which decision makers purchase expert advice, such as when they pay consultants for their services. Research also indicates that decision makers are less likely to discount advice when they trust that their advisors are keeping the decision makers' best interests in mind. Finally, decision makers are less likely to discount advice expressed with great confidence than they are to discount advice expressed with less confidence. In fact, advisors can express confidence in their recommendations as a means to deliberately influence decision makers to utilize their advice.

Decision makers' own confidence in their decisions has also been researched. Research indicates that less confident decision makers typically request more advice than their more confident counterparts. Furthermore, decision makers are more confident in their postadvice decisions when their advisors all make similar recommendations. This agreement is especially important when decision makers use the same information to make a recommendation. Decision makers are also more confident in their postadvice decisions when they receive advice from a greater number of advisors, when decision makers know that their advisors had access to a greater amount of information on which to base their advice, and when

decision makers believe the recommendations to be accurate or otherwise of high quality.

Postadvice decision accuracy has also been investigated. A decision maker's accuracy improves when advisors have access to more information relevant to the decision, when advisors themselves provide the decision maker with more accurate recommendations, and when the decision maker knows how to accurately weight each advisor's recommendation. Decision makers can learn to make better use of advice if feedback about the decision making tasks is available. Specifically, decision makers are better at weighting advice when they receive feedback about their advisors' past accuracy rates as well as feedback about their own past success in accurately weighting advice. Finally, accuracy is highest when both decision makers and advisors possess high levels of conscientiousness and general mental ability.

ADVICE GIVING

The research on advice giving is far less developed than the research on advice taking. Researchers interested in advice giving have typically focused on determining whether advisors and people making decisions for themselves (i.e., personal decision makers) make similar or different decisions when faced with the same problem. Research shows that advisors and personal decision makers make different decisions. Whereas advisors recommend choices that would please *most* decision makers, personal decision makers' choices reflect their own idiosyncratic preferences. In addition, advisors exert more effort when making the decision, are more concerned about the accuracy of their recommendation, and avoid searching for information in a one-sided or otherwise biased manner.

ADVICE TAKING AND ADVICE GIVING IN INDUSTRIAL/ORGANIZATIONAL PSYCHOLOGY

Although advice is likely to be exchanged in virtually all work-related decisions, a number of topics studied by industrial/organizational psychologists stand out as being particularly linked to the JAS research.

Various types of interpersonal relationships at work involve the exchange of advice between parties. For example, mentors often serve as their protégés' advisors. In fact, the support mentors give their protégés, either in terms of psychological or career-related assistance,

can be classified as a form of advice. For example, mentors often instruct their protégés on how to accomplish work goals and give socioemotional support when appropriate. Similarly, when employees enter a new organization, they often go through a socialization phase during which they learn how to become an organizational member. Again, much of the interaction between organizational newcomers and their socialization agents can be construed as one or more types of advisory behaviors (e.g., recommendations on how best to perform one's job). Moreover, socialization often takes the form of unsolicited advice (e.g., when all employees go through the same formal socialization program) but can also often take the form of explicitly solicited advice (e.g., when employees proactively engage in socialization behavior).

Research on employment decisions, such as those occurring during the job search and job choice processes, as well as those occurring during the turnover process, are also related to the research on giving and taking of advice. For example, a new college graduate might ask friends, family, or a trusted academic counselor for a recommendation about how best to decide among a series of job offers. Similarly, older job seekers might ask younger friends for recommendations on how to find job openings in the current job market. Other important employment decisions that seldom occur without the input of others are the decision to retire from one's job or the decision to voluntarily leave one's current job to seek employment elsewhere. In both instances, it is unlikely that employees would not discuss their intentions with family members or coworkers. However, despite the likely prevalence of advice being exchanged in these situations, research on work-related decisions has yet to address what role advice may play in the decision-making process.

JUDGMENT AND DECISION-MAKING PROCESS: HEURISTICS, COGNITIVE BIASES, AND CONTEXTUAL INFLUENCES

How people choose jobs, how employers select and promote employees, how performance is evaluated and rewarded, and many other primary topics of industrial/organizational (I/O) psychology have human judgments and decisions at their core. The study of judgment and decision making is highly interdisciplinary and varied in its research approaches, but behavioral decision making, or the study of how people actually make decisions, has much to offer industrial and organizational psychology.

HEURISTICS AND BIASES

One behavioral decision paradigm that has received much attention from I/O psychologists is that of *heuristics and biases*, pioneered by the seminal work of cognitive psychologists Daniel Kahneman and Amos Tversky in the 1970s. This tradition proposes that observed decision behavior results from several cognitive heuristics, or rules of thumb, that generally produce reasonable and quick results but that can also lead to systematic patterns of error. Many heuristics

have been identified and used to explain judgments in a wide variety of decision contexts. The most well-known heuristics and biases are presented here, with examples of how they can lead to poor decision making in contexts relevant to I/O psychology.

Anchoring and Adjustment Heuristic

An initial estimate or value (anchor) can have an undue influence on final judgments or predictions, as adjustment is often insufficient. For example, the decision on what salary to offer a job candidate may be based on his or her current salary. An employer will use current salary as an anchor and then adjust the figure to make an offer, but if the candidate is presently underpaid, the offer will likely be well below her true value. Similarly, a high-status job title can lead to higher job evaluations because raters have an initial expectation about a job after reading its title and do not adequately adjust after being presented with detailed information about that specific job contradicting that belief. Especially troubling is the finding that decision makers are often not aware of, or actively deny, the extent to which provided anchors influence their judgments, even when they feel they have rejected those anchors as inappropriate or biased.

Availability Heuristic

The perceived likelihood or frequency of an event is based on how easily instances come to mind, through either recall or imagination. This is, of course, a generally reasonable heuristic; more common events should be cognitively more available. But the availability heuristic can lead to error when people selectively attend to especially vivid or recent events at the expense of considering more historical or statistical information. Managers often bias annual performance evaluations when they rely only on their memories, because events in the preceding three months, and particularly vivid events, will be given too much weight relative to performance in earlier months and more prosaic behavior.

Representativeness Heuristic

People also assess likelihood based on the degree to which a situation resembles, or is representative of, their stereotype of that event. Perceived similarity has a pervasive effect on how we perceive other people.

We expect people to resemble our prototype of the category of which they are members, and we judge their suitability for a role based on our prototype of that role. Thus the glass-ceiling effect can be partially explained by the fact that prototypes of executives may not include women and minorities. Although judgments based on representativeness are often accurate, this heuristic also causes people to neglect base rates (the prior probabilities of outcomes) and to be influenced by irrelevant attributes. For example, a number of studies have found that employers evaluate job applicants and employees more favorably when they perceive them as similar to themselves. These similarity judgments are often based on irrelevant factors such as demographics, interests, and general attitudes unrelated to job performance. Most employers view themselves as being exceptionally capable, and the representativeness heuristic causes them to expect people who are similar to them to be equally effective.

Confirmation Bias

People tend to seek out information that confirms their existing beliefs, hunches, or expectations and to exclude or discount contradictory evidence. This is unfortunate, because it is often the search for disconfirming evidence that will yield the most useful insights. For example, if a manager initially has a favorable impression of a job candidate, for whatever reason, he or she will tend to ask interview questions that are likely to support this impression and be much less likely to ask questions that could lead to discovering negative information.

Sunk Cost Fallacy

Our past decisions are likely to bias our present decisions. In other words, we frequently escalate our commitment to a previously chosen course of action, to an irrational level. This has been widely demonstrated in financial decision making, where people who have previously invested money in an option will be more likely to continue to do so even if rational analysis of the current situation would argue against it—in effect, they will “throw good money after bad.” This bias has also been demonstrated in performance appraisal. Supervisors who make the initial decision to hire or promote someone subsequently evaluate that employee more positively and treat him or her more

favorably than will evaluators who were not involved in the hiring decision. The selection of that employee represents a sunk cost (the other candidates foregone) and seems to lead supervisors to continue to see that person more positively (see also *confirmation bias*, discussed earlier), even when actual performance does not merit it.

CONTEXT EFFECTS

Classic economic theory assumes people have well-defined preferences and therefore make consistent choices. Behavioral decision researchers, however, have demonstrated that people's preferences for risk, their discounting of time, and their choices among options with multiple attributes all depend on the particular decision context. In other words, seemingly irrelevant factors that rationally should not affect preferences will in fact do so. As with heuristics and biases, we are typically unaware of the true impact of these contextual factors on our choices.

Kahneman and Tversky also developed the most prominent behavioral theory of decision making under risk: *prospect theory* posits that, in comparing decision options, the selection of a reference point is critical. One major finding of prospect theory is loss aversion; losses are more psychologically aversive than gains are enjoyable. Research on prospect theory, as well as other behavioral decision theories, has established that people's choices are context dependent. The following three types of context effects are of particular relevance to I/O psychology.

Framing

Framing effects result from semantic manipulations, such that the way in which a decision problem is worded influences judgments and choices, even when the underlying problem structure remains the same. Objectively identical options can be framed positively or negatively, depending on what reference point is used. In risky choice, *framing* refers to the well-documented finding that loss aversion leads people to be more likely to prefer a risky option when it is presented in terms of losses (e.g., a one-third chance that no one will lose a job and a two-thirds chance that everyone will lose their job) than when it is described in terms of gains (e.g., a one-third chance that all jobs will be saved and a two-thirds chance that no jobs will be saved).

Framing effects can also derive from the way that problem attributes or goals are presented. For example, layoff survivors evaluate a company more positively when they are given information that emphasizes the criteria used to retain, rather than dismiss, certain employees. Whether an employee is described as having an absence rate of 2% or an attendance rate of 98% can also determine how her performance is evaluated, and when multiple performance attributes for several employees are presented, how this information is framed can determine which employee is hired.

Decoy and Phantom Effects

Logically, the rank ordering of two options should not depend on what other options are considered. A *decoy effect* occurs when the presence of a clearly inferior option (a decoy) alters preferences among superior options. Consider a case in which job applicants are evaluated on two criteria: Applicant 1 receives a high score on criterion A and an average score on criterion B, whereas Applicant 2 is average on A and high on B. If a third applicant (the decoy) is also considered and is high on A but low on B, most evaluators will tend to select Applicant 1. This effect stems from the previously discussed tendency for loss aversion. From the reference point of the decoy, Applicant 1 represents no loss on A and a gain on B. Conversely, Applicant 2 would represent a loss on A, even if the gain on B would be larger. Because losses are especially aversive, the presence of the decoy makes Applicant 1 seem the better choice. If the decoy is low on A but high on B, however, Applicant 2 is more likely to be chosen. In other words, the majority of people will now choose Applicant 2 over Applicant 1 even though nothing about these two applicants has changed. Considering an option that is clearly superior can also influence how inferior options are ranked. A *phantom effect* is an option that becomes unavailable; in a selection context, this could be a job candidate who "got away" by accepting an offer from another firm.

Related recent research using the context of job choice has also demonstrated that the presence of an inferior alternative increases the value associated with the attributes of a dominant alternative. More broadly, increasing evidence suggests that people are influenced more by the set of alternatives being considered and less by the actual overall quality of the options.

People are better at assessing relative value than fundamental value.

Selection Versus Rejection

Many decision tasks in I/O psychology involve preferences among people, such as picking the best candidates to hire or promote, or which employees to retain or let go during a layoff. Determining the best alternative(s) from a larger set can be viewed either as (a) selecting some options, implicitly eliminating the others, or (b) as rejecting some options, implicitly retaining the rest. These two types of decisions seem logically equivalent, but researchers have identified several systematic, substantial differences in how people respond based on whether they are told to reject people or to select them. In particular, attributes compatible with a decision strategy (i.e., positive features when selecting and negative feature when rejecting) are given greater weight.

IMPLICATIONS FOR IMPROVING ORGANIZATIONAL DECISION MAKING

The fact that judgmental biases and context effects can often lead to suboptimal decisions about job candidates, employee performance, compensation, and other important organizational decisions is well established. Note that for many types of decision problems, employers and employees are unlikely to naturally acquire the kind of feedback that would help them improve their decision making. For example, managers who make hiring decisions are unlikely to ever find out anything indicative of how rejected applicants would have fared. To date, however, there has been limited research in how to best mitigate or correct for these potential decision pitfalls, particularly in organizational settings.

A number of books on behavioral decision making for a popular audience are now available, and many business and psychology courses now incorporate some discussion of behavioral decision biases. But there is little evidence that brief exposure leads to any lasting change in how people make decisions. It may seem reasonable to assume that if people simply have substantial incentives to make good decisions, and expend more effort on them, they will be less likely to fall prey to irrationality, but this is not necessarily true. In particular, there has been a great deal of research effort directed toward understanding how

accountability, an important incentive in many organizational decisions, influences judgments. The effects of accountability on decisions are complex, but it has been shown to actually exacerbate some biases. Understanding judgmental biases and contextual influences is, however, the first step toward designing training programs and structuring decision procedures to make poor decisions less likely.

JUSTICE IN TEAMS

Justice in teams represents a specific content area within the organizational justice literature that focuses on how fairness operates in collective contexts. The

majority of the studies in the organizational justice literature examine how individuals form and react to fairness perceptions. For example, studies explore how individuals judge the fairness of decision outcomes, decision-making procedures, interpersonal treatment, and authority communication and how those judgments influence key attitudes and behaviors. Studies in the area of justice in teams acknowledge that those phenomena occur in collective contexts—that what happens to one employee may depend on (and influence) what happens to others.

The justice in teams literature acknowledges an important trend within organizations: the increased use of team-based structures. Recent estimates suggest that between 50% and 90% of individuals work in *teams*, defined as a collection of individuals who work together to complete some task, who share responsibility for collective goals or rewards, and who see themselves as a meaningful social entity. Research on justice in teams tends to focus on three types of research questions: (a) Do the results of individual-focused justice studies generalize to team members? (b) Does the justice experienced by one's teammates have direct or interactive effects on one's own reactions? and (c) Does the justice experienced by the team as a whole influence collective reactions at the team level of analysis?

GENERALIZING RESULTS TO TEAM MEMBERS

The first stream of research that was conducted in the justice in teams literature explored whether the results of studies in individual settings generalize to team members. Studies in individual settings have linked fair treatment by organizational authorities to beneficial attitudes (e.g., trust in one's leader, commitment to the organization, satisfaction with one's job) and beneficial behaviors (task and citizenship behaviors in support of the organization's goals). Those same results have been demonstrated in studies on justice in teams. Some of those studies have taken place in the laboratory, with undergraduates placed into small teams (of three or four members) working on some task or simulation and reporting to an ad hoc leader. Other studies have taken place in the field with larger teams whose members work together for extended periods of time.

Those laboratory and field studies have also examined a subtly different question: Do members react to treatment by organizational authorities by altering

attitudes and behaviors targeted to their teammates? On the one hand, those teammates are not responsible for any unfair treatment the member might have experienced. On the other hand, it may be difficult for members to avoid transferring negative emotions or feelings to teammate-directed reactions. In fact, research tends to show that such transference does occur, with members reacting to unfair treatment by becoming less attached to the team and engaging in less frequent helping of team members. This finding highlights the importance of justice in teams, as unfair treatment can hinder both authority and member-directed attitudes and behaviors.

EFFECTS OF TEAMMATES' TREATMENT ON ONE'S OWN REACTIONS

In addition to providing multiple targets for justice reactions, team settings provide multiple referents for judging fairness. In other words, team members can ask, "Was that decision event fair to me?" and "Was that decision event fair to my teammates?" The second stream of research described in this entry has explored whether teammates' treatment has direct or interactive effects on a member's own reactions. Direct effects of teammates' treatment would suggest that vicarious justice can alter one's own attitudes and behaviors, with members penalizing an authority for treating a teammate unfairly. Interactive effects of teammates' treatment would suggest a sort of social comparison process, as members compare their own outcomes, procedural experiences, or interpersonal treatment with their teammates' experiences when reacting to authorities or decision events.

As with the studies reviewed earlier in this discussion, the stream of research on the effects of teammates' treatment has occurred in both the laboratory and the field. Laboratory studies have manipulated the treatment of an individual participant while also manipulating the treatment of one or more other participants. For example, a participant may be given input into laboratory decision-making procedures but have teammates who are not given that input (or vice versa). Sometimes these studies have included true teammates who are physically present alongside the participant, and sometimes the teammates are merely unseen, fictional others. In contrast, field studies have measured individuals' own fairness perceptions while also gathering data on teamwide fairness levels. For example, an employee may be asked to rate the

amount of input he or she has in decision making procedures while also rating the input given to the team as a whole. Regardless of these differences in method, both laboratory and field research have gathered data on two kinds of variables: own treatment and teammates' treatment.

The studies in this stream of research have sometimes yielded significant incremental effects for teammates' treatment, over and above own treatment, on a variety of attitudes and behaviors (e.g., leader evaluations, commitment, citizenship, performance). However, the effects of teammates' treatment seem to be smaller than the effects of one's own treatment and are more likely to be statistically significant in field research or in laboratory research that creates actual teams. In addition, studies have yielded significant interaction effects that suggest that members consider their teammates' treatment when reacting to their own fairness experiences. In general, the pattern of this interaction is such that consistent treatment within the team is reacted to more favorably. For example, if a member is given input into a key decision, he or she will react more favorably when other members are given the same opportunity. This finding further highlights the importance of justice in teams, as fair treatment must be uniform within the team for members to react in the most favorable manner possible.

JUSTICE AT THE TEAM LEVEL OF ANALYSIS

Given that team members do consider the treatment received by teammates, it seems likely that justice experiences will become one of the more commonly discussed topics in a team setting. Moreover, as team members compare notes about their justice experiences, it follows that a shared consensus may emerge regarding how the team, as a whole, is treated. It is this shared consensus—termed *justice climate*—that is the subject of the third stream of research reviewed in this entry. The emergence of a justice climate can be explained by understanding the nature of a team's social network. The more interdependent a team's work, the stronger the ties that bind members together in their social network. Those strong ties facilitate the mutual exchange of information and interpretation needed to arrive at a shared consensus.

Research on justice climate has occurred exclusively in the field, given that a shared consensus is unlikely to develop in a short-term laboratory environment. Justice climate studies have occurred in a

number of types of teams, ranging from automotive parts manufacturing teams to teams in bank branches to top management teams in international joint ventures. The emergence of a shared consensus regarding fair treatment is demonstrated statistically by showing high within-group agreement on survey measures of fairness. For example, each member may be asked how much input in decision making the team as a whole is given, with responses to that survey question compared across team members. Once a shared consensus has been verified, justice climate has been used to predict the attitudes and behaviors of the team as a whole. For example, fair justice climates have been associated with better team performance, less team absenteeism, increased team citizenship behaviors, and higher levels of team commitment.

Other studies on justice climate have occurred in units that are too large to technically be termed *teams*. For example, studies have examined justice climate within public service plants, hotel properties, and departments in a grocery store chain. Despite the large size and relatively low interdependence of these units, survey measures of fair treatment have still yielded relatively high within-group agreement. Moreover, justice climate has predicted organization-level measures of commitment, citizenship, turnover, and customer service behaviors. The research on justice climate again highlights the importance of justice in teams, as fair treatment can create a shared consensus regarding fairness levels that can influence the attitudes and behaviors of whole units, not just individual members.

SUMMARY

Studies in the area of justice in teams have made a number of contributions to the larger literature on organizational justice. The studies have shown that the treatment experienced by an individual team member has implications for how that member reacts to his or her teammates. The studies have also shown that members take into account the fairness received by teammates when forming attitudinal and behavioral reactions. Finally, the studies have shown that a shared consensus can emerge regarding fairness levels that can affect the attitudes and behaviors of the team as a whole. These studies therefore reaffirm the importance of treating team members in a fair manner.

LABOR LAW

Labor or union law refers to the body of laws, regulations, and case law that governs unionization and collective bargaining in the workplace. It is distinguished from employment law, which deals with employment contracts, workplace discrimination, and other private legal issues. Most industrialized countries have enacted labor laws, but those laws may vary across countries or even within a country. Labor relations may be governed by both national and regional labor laws—in Canada, for example, there are provincial labor laws. This essay focuses on U.S. federal labor law governing labor relations in the private sector.

The National Labor Relations Act (NLRA) is the basic federal law that governs unionization and collective bargaining in the United States. Originally enacted in 1935, at which time it was also called the Wagner Act, the NLRA has undergone several significant amendments, most recently in 1974. The NLRA regulates labor relations in almost all private-sector businesses that participate in interstate commerce. The NLRA does not cover public employees (who are covered by state labor relations laws), agricultural employees, or employees of railroads and airlines. Labor relations in the latter industries are governed by the Railway Labor Act.

BASIC PRINCIPLES OF THE NLRA

The collective bargaining system established by the NLRA has five basic principles: (a) employee

choice, (b) majority rule, (c) exclusive representation, (d) appropriate bargaining unit, and (e) labor and management determination of terms and conditions of employment. The principle of *employee choice* means that employees in an appropriate bargaining unit choose whether they wish to have a union represent them for collective bargaining purposes and, if so, which union. The principle of *majority rule* means that the employees' choice of representation is made by a majority of the employees in the bargaining unit. If a majority of the employees in the bargaining unit do not select representation, the employees in that unit cannot be represented by a union.

If a majority of the employees in the bargaining unit choose union representation, the principle of *exclusive representation* comes into play. Under this principle, the union selected by the majority of the employees in the bargaining unit represents all the employees in the unit, regardless of whether the employees support unionization. The employer, in turn, has a legal obligation to bargain with the union in good faith regarding the terms and conditions of employment for the represented employees.

The fourth principle is the *appropriate bargaining unit*. The selection process for unionization takes place among the employees in an appropriate bargaining unit. An appropriate bargaining unit is a grouping of employees who work for a single employer and have common employment interests. They may be employees who work in a company facility, an occupational group, a department, or a craft. Employees who have a community of interest have similar supervision, pay structures, tasks, hours of work responsibilities, and work location.

The fifth principle is *union and management determination of terms and conditions of employment*. The employer has an obligation to bargain in good faith with the union representing its employees, and the union has an obligation to bargain in good faith with the employer. Neither party has an obligation to agree, however. The terms and conditions of employment are determined by the parties' negotiations, which are influenced by the bargaining power of the parties, manifested in their use of economic weapons such as a strike, lockout, or employer replacement of strikers. The purpose of these economic weapons is to move the parties toward agreement, even if one party concedes. The law does require that the parties reduce an agreement to writing. An agreement in writing is generally enforced through a grievance procedure that ends in binding arbitration.

BASIC RIGHTS UNDER THE NLRA

The NLRA gives employees the right to bargain collectively; to form, join, and assist unions (called *labor organizations*); and to engage in concerted activity for other mutual aid or protection. Thus, the NLRA is not limited to employees' attempts to unionize; it also protects the rights of employees to refrain from any activities related to collective bargaining or unionization.

Only those who are considered employees for the purposes of the act may exercise their rights under the NLRA. Supervisors, managerial employees, independent contractors, persons whose jobs are related to an employer's labor relations function, and persons who are employed in industries that are not covered by the NLRA are not considered employees for the purposes of the NLRA.

ADMINISTRATION OF THE NLRA

The NLRA is administered by the National Labor Relations Board (NLRB), an administrative agency of the federal government. The NLRB consists of five members who serve staggered five-year terms. The NLRB members are nominated by the president and must be confirmed by the U.S. Senate. By the third year of a president's term, he or she will have appointed a majority of the board members. (There is a custom, however, that no more than three board members may be affiliated with one political party.) With its limited terms and appointment and confirmation

process, the NLRB is designed to be an agency that changes in its composition—and to some extent, its views on labor relations—with the changing political climate of the country.

The NLRB has two main functions: determining representation and preventing unfair labor practices. In its representation function, the board determines whether a unit of non-union employees wishes to be represented by a union. Upon a showing of substantial interest—generally demonstrated by at least 30% of the employees in a bargaining unit signing union authorization cards designating the union as their collective bargaining representative and presenting the cards to an NLRB regional office—the board will initiate its representation procedures. After resolving any disputes regarding the bargaining unit, representation is typically determined through a representation election. For example, from October 1, 2002, through September 30, 2003, the NLRB conducted 2,797 representation elections. Employees chose representation in 1,458 of those elections (52.1%) and did not choose representation in 1,339 elections (47.9%).

The board's second major function is to prevent unfair labor practices. An employer commits an unfair labor practice under the NLRA when it discriminates, interferes with, or coerces employees who attempt to exercise their rights under the NLRA or when it refuses to bargain with a union that represents its employees. Examples of unfair employer labor practices include the following:

- Discriminating in hiring, promotion, or discharge in order to discourage membership in any labor organization
- Retaliating against an employee for filing charges or testifying under the act
- Interfering with union affairs by sending a management representative to spy on worker organizing meetings
- Attempting to control a union by helping a certain candidate (favorable to management) win election to a union office
- Refusing to bargain in good faith by changing the terms or conditions of employment without employee input during the term of the collective bargaining agreement

A union commits an unfair labor practice when it refuses to bargain in good faith with management, discriminates against an employee who wishes to exercise his or her right to refrain from union activity,

or commits any one of several other types of offenses. Examples of unfair union labor practices include the following:

- Refusing to process a grievance because an employee has criticized union officers
- Threatening employees that they will lose their jobs unless they support the union's activities
- Fining employees who have validly resigned from the union for engaging in protected activity following their resignation
- Refusing referral or giving preference in a hiring hall on the basis of race or union activities

IMPLICATIONS FOR INDIVIDUALS AND ORGANIZATIONS

The NLRA and U.S. labor laws provide an extensive formal structure that ensures employees' right to engage in collective or concerted activity for the purpose of improving their conditions in the workplace. The NLRA also protects individual employees from being unduly coerced into engaging in concerted activity. Though the NLRA clearly outlines employees' individual and collective legal rights in the workplace, its impact on employees' actual workplace experiences is less clear. For example, although the NLRA formally provides workers a greater collective voice in workplace affairs, research shows that union workers report having less actual influence in their workplace than non-union workers.

The NLRA has important implications for the employment practices of both unionized and non-unionized employers in the private sector. Among unionized employers, collective bargaining agreements between an employer and a union commonly include a wide range of clauses that affect the employer's human resource practices, such as wages, benefits, hours of work, job security, discipline, arbitration, the permissible pool of employees eligible for promotion and transfer, training, and criteria for evaluating performance. The terms of collective bargaining agreements are subject to negotiation, but once they are agreed to, collective bargaining agreements create binding obligations that, if unilaterally disregarded by the employer, may result in an arbitration decision that is enforceable in court.

The NLRA's implications for employment practices in non-union workplaces, though less extensive, are still significant. For example, a non-union employer's workplace policy may violate the NLRA on its
